PLANTING OPINION.

A WEEKLY JOURNAL

(WITH MARKET SUPPLEMENT)

WRITTEN BY PLANTERS FOR PLANTERS.

VOL. III.] COONOOR, SATURDAY, JANUARY 8, 1898. [No. 1.

CONTENTS.

	PAGE
SEASON REPORTS	1
NOTES	2
LETTERS TO THE EDITOR	6
GENERAL ARTICLES—	
Soil Renovation	7
Anise	9
Utilisation of Bone Manure	9
Pineapple Fibre	9

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 14th January, 1898.

Kadur.

MUDIGERE, 29*th December* 1897.—*Weather.* Fine, and no rain clouds about. Rain now, though it would help to ripen crop, would force spike and wood, with a chance of three hot months before us. *Crops.*—Picking still going on on most estates. The bean is very good this year, with a fair amount of pea-berry. *Plant-diseases.*—Old *Hemelia Vastatrix* is spending Christmas with us. Bad luck to him. *General Health.*—The festive season has been saddened by the news of Mr. Digby Brett's death at Koppa—a man so well-known and much-loved by all in the district. He was for many years the President of the North Mysore Association.

S. E. Wynaad.

DEVALA, *5th January.—Weather.*—From the 22nd to 29th December at nights very cold, and during the day the sun shines very brightly. On the 30th December we had rains both day and night, and since it is very cold at night and hot during the day. *Crops.*—The stripping is finished, and the paddy harvest among the ryots is in full swing. Grain: salt 8, rice 8, cholum 18, and ragi 18 seers per rupee. *Health.*—Fever is very prevalent. *Labour.*—Sufficient.

Nellampatty (British).

5th January.—Weather.—Clouds began to gather on 26th, and the strong land wind which had been blowing ceased. On the night of 30th December, 90 cents fell here, but some places got much less, and I fear no good will result from it as far as next year's crops are concerned. Here it is all right for clearings. *Coffee.*—In most cases two-thirds are gathered, and in a few cases pruning is being done. *Plant-diseases.*—Coffee looking very fit everywhere. *General Health.*—Good, save for colds. *Labour.*—Plentiful. A great many estates will pay off at the end of January this year, I hear. *Interesting Items.*—Christmas festivities are over, (thank Heaven!) and we are again settling down to the usual routine. On New Year's day the bachelors entertained the married folks at a picnic, which was a great success, and the general wish is, Many happy returns of the same.

Nilgiris.

KOTAGIRI, *7th January.*—The rainfall due for the last quarter of the year is—

in Oct.	in. 14·19	28·03
„ Nov.	„ 9·98	
„ Dec.	„ 3·86	

which is very nearly equal to the rainfall due for three-fourths of

the year, from January to end of September, but the N.-E. Monsoon hardly made any show; it was marked by long spells of fine weather in October and November, and December was especially dry and cold. The rainfall gauged here was only

in Oct. in. 4·40
„ Nov. „ 5·32 } 11·72
„ Dec. „ 2·00

and although the fall was ahead of the average due by end of September, the year closed, owing to the failure of the N. E. Monsoon, with a total of only in. 54·14 against an average due of in. 58 92. *Crop.*—Where there is any, has been coming in steadily, free from rushes, most estates having over ½ in by X'mas day; it runs heavy, and estates generally into the three figures show a markedly good outturn this season.

NOTES.

Tea-seed in Ceylon. If all the seed imported in Ceylon this season is planted up, the increase in acreage will be enormous, well over 30,000 acres; and this, too, in face of a rising exchange and a falling market.

Coffee in Queensland. A Russell River planter recently sold some three tons of coffee in the local market at 9*d.* per pound in parchment. It is stated that even at 6*d.* per pound, a good margin of profit would remain!

Wara fibre (Calatropis gigantea). Some ten years ago a sample of this fibre was sent home from Ceylon, and was valued at £36 to £38 per ton, being classed as equal in value to the finest rhea. It grows well in low-country districts on poor soil.

Indian tea exports. The total exports from Calcutta from the 1st April to the 30th November, 1897, were a little under 113½ million pounds as against 112⅓ and 104½ in 1896 and 1895, respectively. The total Ceylon exports from 1st January to 16th November, 1897, were 98⅕ M. against 92¾ M. in 1896. The sailings of Indian tea to Australia are about 300,000 lb. more than last year.

Tea-sales in Colombo. When public sales were commenced in Ceylon in 1890, the amount disposed of was nearly 6 million pounds, or 12·7 per cent. of the total shipments. In 1894 it rose to over 15¾ M., or 18·6 per cent., while in 1897 the *Times of Ceylon* estimates it as exceeding 26½ M., or 22·7 °/₀ of the whole. In 1896, however, the percentage was slightly greater, being 23 per cent. of the total shipment.

Coffee in East Java. It will not be long ere East Java will come into the prominence it deserves as an exceptionally good coffee country. While labour is still high, it has been reduced from 90 cents per day to 50, or say 10*d.*, while crops are excellent. The land is rich, the labour good if expensive, easy rent and taxes, nothing to pay for five years, and then about 2*s.* 3*d.* per acre rent with 2 per cent. tax on produce and the prices A 1.

Annatto. Prices for annatto (the seed of *Bixa orellana*) are rising, and planters might profitably take up the cultivation of this shrub on a small scale. Sides of roads, bits of abandoned land and so on could be used for the purpose at a small expense. The demand is not unlimited it is true as in the case of many other minor products, the yield from a number of products more or less insignif in themselves would add sensibly to the profits der from the staple.

Banana flour. *Apropos* of our recent artic Banana flour, it is mentioned late number of the *Borneo Herald* that the Perak Resid Annual Report for 1896 states that an experimental e prize for the production of this commodity was starte one of the European Coffee planters in that State du the past year. The Resident writes hopefully of th pected result, and we shall watch the outcome with interest. The secret of success seems to be in effi dessication of the fruit before pulverizing it.

Mexican plantations. In spite of the phenomenal pression in the prices of Ame coffee, a great deal of energy is being displayed by Bu syndicates in the exploitation of Mexican coffee-lands large London Syndicate, named "The Mexico Produce Estates Syndicate" has recently been formed, with offic 138, Winchester House, London, E.C., who have deputed experienced Ceylon planters to report on the capabiliti the country. If their report confirms others already in hands of the Syndicate, operations on a very large scale expected.

The maple tree. Attention is being drawn no the commercial value of the m tree in Canada, remarks the *Produce World*. It w certainly appear that as an increasing source of produc business, the maple is not properly understood. It is st on good authority that maple trees, when the sap is corre treated, yield quite ten dollars per acre. Besides this, t is the value of the timber too. Exports of maple su have already been made to the amount of about $50,000 annum, but this is a trifling revenue to what might obtained.

The cross-cut saw in clearings. We were surprised to note i Upper India contemporary that supposed by tea planters in As and Cachar that cross-cut saws are only useful for cut matured timber. An absurd fallacy this, which we are to note the *I.P.G.* has exposed. We would remark, howe that it signifies nothing whether the trees be perpendic or slanting, small or large in girth; cross-cut saws ca far quicker and neater work than axes. The only thin be remembered is to have the teeth set properly and to enf upon the coolies the necessity of *pulling* and not push the saw while cutting.

The B. C. A. planting industry. The planters of British Cen Africa have something at leas be thankful for, in that the Gov ment recognizes the importance of the industry to extent of engaging botanists, or rather an expert a horticulturist, on their behalf. Besides undertaking general analysis of soils, he will analyse new produ investigate plant diseases and so on. We note that local Chamber of Agriculture and Commerce have as

their Government to establish an experimental estate in order to test in a practical way the suitability of economic plants for cultivation in B. C. A.

Book-keeping for young planters.

A correspondent writes us as follows: "I should be much obliged if you could let me know where I could get a simple method of keeping estate accounts, including check roll, cash book, ledger and journal. I got a book from you [A Ceylon book.—ED.] on book-keeping in Ceylon, which, however, does not enter into the details of check roll keeping." We would suggest our correspondent applying to his nearest neighbour for instructions as to keeping his check roll, pay list, cash book. Ledgers and journals are rarely kept on estates, but if he studies the work, he mentions, he will find full instructions.

Trade allowances on half chests of tea.

Writing to an exchange, a correspondent makes the following very sensible suggestions:—

"One pound per package on full chests amounts to, say, 1 per cent., each chest containing roughly 100 lb. tea, but 1 lb. a package on half-chests amounts to 2 per cent. This is most unfair for several reasons. Packing in half-chests is more expensive per pound than in full chests. Half-chests are more suitable for grocers, and, therefore, more attractive for buyers. Several producers are obliged to pack in half-chests, owing to the distance they have to send their tea on coolies' heads to the nearest cart road. Thus, in fairness, half-chests should be taxed at a lower rate in London, as they cost more in proportion than full chests; at any rate they should not be taxed by the buyer at a *higher* rate than full chests, which is being done at present."

Vanilla.

Cultivate vanilla, wherever soil and circumstances permit, is the advice to be gathered from the report of Mr. H. Cockburn Stewart, Administrator of the Seychelle Islands, who, in forwarding his annual report, gives special prominence to the vanilla industry, which is experiencing quite a boom. The crop last year was the largest on record—63,000 lb., and the prices obtained on the London and Paris markets were such as to delight the hearts of the cultivators. "Nothing pays better than vanilla," remarks the head of the local Government, and when the islands are still further opened up by roads, he anticipates a large increase of the acreage under vanilla cultivation.

New Zealand hemp: (Phormium tenax.)

The hemp industry is rapidly developing in New Zealand, and seems to be a highly remunerative business to both growers and manufacturers. Of late prices have been falling, and a Commission has just been appointed to enquire into the causes of the fall, and to ascertain whether the industry could not be further developed. In 1870 5,470 tons of the fibre were exported, of the average value of £24; in 1880 both quantity and value fell enormously, 915 tons being exported, valued at £17 per ton. In 1890 the export rose to 21,158 tons with the slightly increased value of £18. Good grades have been sold as high as £38 per ton. The chief need is a machine to prepare and sort the fibre efficiently, to meet which a prize of £1,750 was offered up to the end of last year.

Rubber plantations in Sumatra.

Numerous India-rubber trees are growing on the east coast of Sumatra in a wild state, and the natives have collected large quantities of rubber to the great damage of the rubber-trees, which have become debilitated and in some cases extinct. Within the past few years, wealthy Holland companies, says the *India Rubber World*, have created rubber plantations, and in the Kasim district a not unimportant market in Sumatra rubber may be expected in the near future. An idea may be had of the remunerativeness of such plantations when it is guaranteed by the directors of the companies that 100,000 rubber trees will clear annually, above all expenses, from 500,000 to 600,000 marks. The editor of the *Gummi Zestung*, in which we find this note, expresses very grave doubts of such figures being realized.

Nutmegs.

A tree that might be profitably introduced on plantations not over 4,000 feet is the nutmeg, which grows and crops luxuriantly in the Burliar (Nilgiris) Experimental Garden:—

"They grow on small trees generally not over twenty feet high. The flowers are very much like lilies of the valley. They are pale in colour and very fragrant. The nutmeg is the seed of the fruit, and the mace is the thin covering over the seed. The fruit is about the size of the peach. When ripe it breaks open and shows the little nut inside. The trees grow on the islands of Asia and tropical America. They bear fruit seventy or eighty years, having fruit upon them all the season. A fine tree in Jamaica is said to have over 4,000 nutmegs every year. The Dutch used to have the whole nutmeg trade, as they owned the Banda Islands, and conquered all the other traders and destroyed the trees. To keep the price up, they once burned three piles of nutmegs, each of which was said to be 'as big as a church.' Nature did not sympathise with such meanness. The nutmeg pigeon, found in all the Indian islands, did for the world what the Dutch had determined should not be done—carried the seeds, which are their food, into the surrounding countries."

The local price at Burliar, we may mention, is three annas per dozen.

Wash-holes and prunings.

An old planter writes strongly to the *Ceylon Observer* on the subject of preventing wash. Water holes he condemns as not only being absolutely useless, but positively harmful. The holes in question were 3 feet $\times 1 \times 1\frac{1}{4}$; unluckily the distance apart is not given. We feel convinced that if done between every few trees as in South India, the disastrous results he relates would have been altogether avoided. He writes:—

"There came a heavy downpour of rain, after a few days light rain: here and there, one of the holes became full and commenced to run over; this caused the next one below it to do the same with increased volume; each succeeding hole added volume and force to the rush of water. Hundreds of tons of soil were washed away, down into the drains, roads and ravines. The lines in that field ran as perpendicular as the hill would permit; consequently the scour was chiefly down between the lines of trees, but in many places the trees were left on stilts! I give this one particularly bad instance. But I can point out hundreds of acres of land now in tea (formerly in coffee when the holes were cut) and the ledges still remain (two feet square or so) showing what was the bottom of the old holes; there being the original hill slope between these ledges. All the soil excavated was soon washed away, once the holes began to fill and became shallow enough to run over in wet weather."

China's prospects.

In a lecture before the London Chamber of Commerce, Mr. George Jamieson, H.B.M.'s Consul at Shanghai, said: "It is asserted, and I do not doubt it, that if foreigners were allowed to introduce machinery into the tea-growing districts and superintend the preparation of the leaf, China tea could even yet hold its own against the best that India and Ceylon can produce. But no such prospect I am afraid

can be held out. The treaty gives us the right to buy from the Chinese such tea as they prepare, but not to grow and prepare it ourselves. I was consulted, just before leaving Shanghai, by a small syndicate who were very desirous of getting machinery introduced into one of the large tea-growing districts as an experiment. The proposal was to co-operate with a native company, who would be the owners of the plant, and employ as superintendents the necessary foreign staff. The plan seemed feasible enough, but it came to nothing. The native teamen had not the courage to risk their money. They did not know what the officials would say, or probably enough they got a hint that the officials would not have it, and so the whole thing fell through."

A New York-Indian line.

A regular direct steamship service between New York and India has been arranged for, the first sailing being set for November 27th by the *Sahara*, a vessel of 4,089 tons, going *via* the Suez Canal, and taking freight for Aden, Persian Gulf, Bombay, Malabar Coast, Ceylon, Madras and Calcutta. She will be followed by monthly steamers. The new service is of especial interest, inasmuch as it is the first direct regular line to India from New York. Most India business has heretofore been handled *via* Great Britain and Mediterranean ports, with occasional sailings by tramp vessels. The new line is established with the definite purpose of developing trade, the agents and managers believing that present trade conditions were ripe for the enterprise, and also feeling confident that with regular facilities the trade will increase. The advantages will be especially felt by American manufacturers, who can thus sell on samples, and conduct their business with greater convenience. The outward cargoes will naturally be of a more or less general character, but steel rails and railroad material will figure as one of the most prominent items. Bucknall Bros., of London, are the managers of the new line, and Norton & Son the New York agents.

Essential oils.

Considerable attention is now being paid to cultivation of flowers for manufacture of essential oils, especially in such countries as Victoria, where climatic conditions are such as to make this industry profitable. In an article contributed to a contemporary, W. Lodian, C.E., recommends a more extensive cultivation of flowers in India, and considers it probable that, with combined advantages of cheap labour and good climate, such an industry would be profitable in this country. At present, many essential oils used in Europe are obtained from France, Italy, and America—United States. Some prices are quoted as value per acre under cultivation, of some commoner flowers; bitter-orange blossom, £60 to £80; jasmin, £20 to £30; roses, £70 to £90, and peppermint, £45. Mr. Lodian gives a short account of methods usually adopted for preparation of essential oil, such as "enflourage" process and extraction by methyl chloride, special attention being directed to points which are likely to be overlooked by a beginner. Farmers are also recommended to keep themselves well acquainted with modern literature on this subject, in order to be able to take advantage of various improvements suggested by experts from time to time.

Estate and London bulking.

From the abstract of the proceedings of the General Committee the Indian Tea Association, dat 6th December 1897, we note that in his letter of 22 October the London Secretary stated that Mr. Lipton h asked him for an official explanation as to the meani attached to the words "bulked in the country of produ tion," which now appears in clause 4 of the Public Sa Condition, and he had replied that it was now provid that all teas sold under these conditions should be proper bulked either in the country of production or in Londo so as to allow a fair sample to be drawn of the whole brea out of any individual package, and he pointed out that t operation of "bulking in the country of production" w understood to be precisely the same as "bulking in Lo don," but the tea having been packed while fresh off t fire should be in a much better condition to retain i strength, freshness and flavour than if exposed for a da or longer, to the damp atmosphere of the London Docks.

It was decided to issue a further circular to all membe on the subject of bulking in the factory, and the matt was to be again brought up for discussion next season.

In his letter of 12th November, the London Secreta enclosed copy of a letter from Messrs. Davidson & Co., which that firm wrote: "We feel confident that in the cour of time, if the bulking is attended to carefully on t estates, re-bulking will be done away with entirely London."

The Quarterly Sales of Cinnamon.

At the public sales held Monday, the 29th November, a mo than usually large quantity Ceylon was offered, says the *H. & C. Mail*, embracing 3,1 bales altogether, of which the bulk, about 2,500 bales, co sisted of "unworked" parcels, and these were disposab only at a reduction of ½*d.* to 1*d.* per lb. from the rates pa in August, ranging from 7*d.* to 11*d.* and 1*s.* 1*d.* for coars woody, and thirds to fine firsts and superior. The sma proportion (between 500 and 600) "worked" cinnamo however, met a far better reception, and was briskly co peted for at stiffening prices. Favourite marks especiall commanded higher prices, to 2*d.* above the former quot tions, and for a single lot of extra choice quality a rise 6*d.* per lb. was obtained at 2*s.* 4*d.* Other garden growt fetched 11*d.* to 1*s.* 7*d.* for ordinary to finest firsts; 10*d.* 1*s.* 4*d.* for seconds, with superior plantation ditto at 1*s.* 7*d* also 9*d.* to 1*s.* 5*d.* for common to very best thirds; and 8½ to 1*s.* 3*d.* for low to fine fourths, with broken (in eig boxes) at 10*d.* to 11½*d.* per lb. Cinnamon chips exhib larger clearances for the present year, and only moderat stocks are left over; but 1,010 bags put forward went o without any noticeable improvement in value; chips at 3 to 3¼*d.* with clippings, cuttings, quillings, pieces, and broke quill from 9*d.* to 11½*d.* to 1*s.* 1*d.* per lb. The series periodical sales for 1898 are arranged for Mondays of th following dates: February 28, June 6, August 29, an November 28.

The low price of coffee.

The price of the lower grades coffee has not been paralleled sinc 1848, says the *Grocer* of 4th ultimo. In America, where th supplies are drawn from an area less wide than ours, th depression has caused anxiety, and our American Exchange

have recently been somewhat exercised about it, prices of Brazil coffees having ruled lately at the lowest figures recorded in the history of the trade. In December, 1882, February delivery sold in New York at 5·24 cents, but since that date until the current year the range has been from 6⅞ cents to 19 cents. This year a gradual decline set in, and three weeks ago November was quoted on the New York Exchange at 4·45 cents. The explanation of the decline is, of course, the large supply. There have been two consecutive large crops, and the promise of a third. Large profits some years ago induced the Brazil growers to plant immense numbers of new trees. It takes five years before a coffee tree produces; but the new trees are now coming into bearing. Although the world's visible supply is large, being estimated at 6¼ million bags a month ago, as compared with 3¾ million bags last year (the largest since 1890), the indications are for a further increase, and it is expected that the enormous number of seven million bags will have been received in the States by next New Years's day. The estimate of the current crop is over nine million bags, whilst that of next year is also expected to be large. Thus far the present year has surpassed last, which was the largest ever known. There is, therefore, every probability that the American dealers will have to lay their account with a continued prevalence of cheap coffee.

Croton tiglium.

The seeds of the *Croton tiglium*, a plant which grows wild all over Lower and Eastern Bengal, according to the *Planter*, are now in large request and are sold at home at £1 per 1000, and larger quantities at reduced rates. It remains to be discovered, however, what has created the present demand for them, for this appears to be a trade secret so far. The plant will grow and thrive on any soil, no matter what the quality of it, and there is no reason why its cultivation should not be introduced on abandoned portions of plantations. It will be a wise precaution, though, to ascertain whether the price of the seed is susceptible of any material variation in the market. The seeds are known to be of a very unctuous nature and there would consequently be considerable loss in weight in transit to foreign markets, due to fermentation. The better plan would be to export the oil which is extracted from the *croton pavana*. There would be an additional advantage in following this method as the oil-cake obtained in the process of seed crushing would find a ready sale as manure. It must be remembered, however, that on account of its highly poisonous nature it is not used to feed cattle on. Doctors and druggists know the value of the oil as well as its efficacy in certain maladies to which humanity is heir, a single drop being sufficient, which no doubt enhances its value. The tree will grow from the sea level to an elevation of 3,000 feet and even over. Once a week a cooly shakes the tree and picks up from the ground what has fallen off, puts the pods in the sun, shells them, and gives another drying, which is all that is required. A net profit of about one shilling per tree per annum has been realized from full grown trees.

A large Company.

The most ambitious Ceylon tea company that has yet made appeals to the British investor, says the London correspondent of a Calcutta exchange, is the General Ceylon Tea Estates, Limited, which has an authoized capital of no less than £400,000 and invites subscription besides for £140,000 five per cent. Debentures. The capital is divided equally between five per cent. Preference and Ordinary shares, of which £135,000 Preference and £115,000 Ordinary are now to be issued. The purchase price of the estates is fixed at £363,500.

There is in the prospectus an elaborate hypothetical estimate of profits, which when molten down comes to this: if the tea is sold at an average price of 7½*d.* per lb. and is laid down in London at 5*d.* (including all costs of sale) there will be 2½*d.* per lb. profits, assuming that this hypothetical (one might say, prophetical) estimate prove correct, the purchase price is ever so more than eleven years purchase and, in view of recent results, far too high. But the estimate is distinctly open to criticism. Under the head of coffee we learn that the profits from 143 acres are estimated at £2,686 or over £18 per acre. If the gross value of the coffee produced amounts to that sum the proprietors of the 143 acres will not have done amiss. Then there are large sums (£2,500 and £1,700 set down as the annual profits on sales of tea seed, and on the purchase and manufacture of teas from adjoining estates, respectively. In support of these figures we have nothing more tangible than that "from a careful consideration of the figures given in connection with the estates the Directors consider that the calculation is a reasonable one." Apart from this assurance of the Directors, which surely it would have been well to support with more than the one single fact that the tea crops of the estates to be bought were last year 1,896,917 lb. I should have been disposed myself to estimate the profits, by comparison with what has been done on other properties whose accounts have been published, at little more than half the figures given: and I should be inclined to fear that even the £15,100 necessary to pay Debenture and Preference interest might not be forthcoming.

Aspect for coffee plantations.

Experience has demonstrated, says the Coorg correspondent to the *Planter*, that for coffee a Western is superior to an Eastern aspect. A Northern is best of all, especially if it is protected by a ridge from the sweeping gusts of east wind which prevail at this time of year, in spite of the fact that Mr. McIvor, of Cinchona fame, held the opinion that a Southern aspect was undesirable for growing cinchona, coffee, &c., owing to its being subject to extremes of temperature, because during the sunny months the sun has a Southern declension, and it is therefore exposed to the full force of the sun's rays during the day, while during the night it rapidly radiates its heat and becomes so chill as to be harmful. In spite of this expert's opinion a Southern aspect hereabouts, if protected from the east wind, is superior to an Eastern aspect. If unprotected, it is probably worse. It will be correctly inferred from what has been said that it is the dessicating east wind that makes all the difference between one aspect and another. It appears to peculiarly favour the hatching of the borer insect's eggs. Parts exposed to the full force of its baneful influence, if not adequately protected by shade, have been completely wiped out, probably because the trees are blown to ribbons, and the stems and the ground become fully exposed to the sharp rays of the morning sun, which, in conjunction with dessicating effects of the wind, are sufficient to promote the

requisite temperature for the successful hatching of the borer insect's eggs. It is of the utmost importance, therefore, that all parts exposed to the east wind should be well protected by shade, and when thinning out shade, the utmost caution is exercised in all such parts, much more shade being left upon them than on the other parts.

Writing on the same subject, the well-known Ceylon planter, Mr. E. Ernest Green, draws attention to the little understood fact, especially in the Island, that forking, properly carried out, actually prevents wash. Clods must not, however, be inverted. The fork should be driven in to its full depth, and the soil merely loosened. The chief cause of wash is the inability of the rainwater to penetrate the ground fast enough when the surface soil is firm and close. Directly the soil is loosened by the proper use of the fork, the rain will soak in as it falls, and there will be no accumulation of surface water to rush down the slopes transporting valuable soil in its progress. The plants also will benefit by the well-known valuable properties of rainwater and by the more perfect aeration of the soil. In connection with both the prevention of wash and the closing of drains, Mr. Green draws attention to a very novel plan that he has been lately adopting, and which has so far proved most satisfactory. This is, to fill up all the drains evenly with the prunings immediately after a field has been pruned. Paradoxical as it may seem, this really prevents the disastrous blocking of drains that so often occurs during a heavy plump of rain. There can be no accidental heading back of water. Any solid matter that falls into the drain rests where it falls—above the prunings—and is not carried along to form a dam at the first obstruction. The water filters through the rubbish, depositing any soil it has brought down, and trickles slowly away below, much of it finding its way into the subsoil. The repeated clearing out of drains is no safeguard against a block. The cleanest drain is at the mercy of the first rock that rolls down the hill. He pleads the following advantages for his method :—

1. The saving of soil: the water being filtered in its passage through the rubbish.
2. A great saving in expense: there being no necessity to clear out the drain until the time for the next pruning, when the accumulated soil and decayed vegetable matter will be spread over the surface below the drain, and the drain will be recharged with the new prunings.
3. The avoidance of any accidental block at one spot, with its consequent leading back of water and overflow.
4. Benefit to the tea by the freer percolation of water in its slower flow along the drain; and by the application of accumulated soil and humus.
5. The convenient disposal of the troublesome prunings.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2.000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

LETTERS TO THE EDITOR.

TO REAR DUCKS.

SIR,—Can any of your readers tell me how to rear duck I get the ducklings *hatched* all right, but they gradually die one, two or more a day; and out of over fifty, I havn't reared this year. I don't let them run about much, and feed them ragi, bran and the "nootchoo" of rice. They get a sort "staggers," and die slowly.

DUCKLING

WORMS IN COFFEE ROOTS.

SIR,—I thank "D." for his letter in reply to my que and regret that, through one cause or another I have been delay in replying to him. The day after the paper with his let came, I "shikareed" for the worms, and managed to secure fo of them, more dead than alive. These I meant to send to you spirits, but a neighbour turning up just then I forgot, and ne morning they were dead and dried up like sticks and fell pieces when handled. Shortly after my letter to you I w advised to try lime for the trees—a large handful, well "kubike in round the plant; this I did with evidently the best results, the damage has stopped spreading as it was doing before, a plants that were only beginning to droop are fast recoveri Some were, I fear, too far gone when the lime was applied, a are dead or dying. Two or three times I have taken up pla that were looking sick, and in all cases found the roots had be eaten as I described in my first letter, but only once found t worm, and it was almost dead, and I think past doing furth damage. The clearing in which this pest appeared had be *lightly* burned last year. No manure was put to the pits whi were filled with black jungle soil scraped from all around the If I again find the worm, I shall at once put it in spirit a send it to you.

On one tree's roots I found the skeleton of a large grub, a on another occasion found in a pit two little white grub, b although grub may have had a hand in it, I am convinced t damage was done mostly by the worm I described, and that t liming has saved a lot of good plants. I shall be glad to ha the opinions of others on the matter.

"YOUNG PLANTER."

TERRACING vs. DRAIN-CUTTING.

SIR,—In response to your invitation to give comparati estimates of the cost of terracing and of drain-cutting in h plantations, I send you the following :—

The cost of both systems depends on, and increases wit the steepness of the hill slopes to which they are applie Assuming an AVERAGE slope of 1 in 2, or 30°, which is, if an thing, above the actual average of ordinary plantations, a taking a width of four feet for each terrace, or, say, fifty terrac to an acre, the area of cutting an earthwork required to gi a horizontal width of four feet would be that of a triang whose base was equal to two feet, *i.e.*, half the width of t terrace, and whose height was equal, at the assumed slope, one foot. This area is one square foot, and would represe the cutting required to form the inner half of each terrac The outer half, of equal area, would be formed by the sp earth excavated from the inner half, and would not be separate paid for. Consequently the amount of earthwork required be paid for to terrace an entire acre would be $50 \times 210 \times 1 = 10,5$ cubic feet, and there would be no annual maintenance.

Now to provide the same area, at the same slope, with a syste of drains placed 40 feet apart, and capable of carrying off a fo depth of water with two square feet of waterway, the area cutting required for each drain would be about three square fe And assuming a single cross or up and down drain to each ac the total number of drains would be six. Consequently t earthwork or excavation required to be paid for to drain o

acre would be $6 \times 210 \times 3 = 3,780$ cubic feet. If these drains are supposed to be annually cleared of an amount of silt only just equal to their capacity, the total earthwork required to be paid for in only two years would be $3,780 + 2 \times 3,780 = 3 \times 3,780 = 11,340$ cubic feet, or 8 per cent. greater than that of the terracing. Under the same conditions with a 1 to 1 or 45° slope in the soil, which is about the steepest that would ever be cultivated, the quantity of earthwork to be paid for in terracing an acre of land would be $50 \times 210 \times 2 = 21,000$ cubic feet, while to cut drains in it the quantity would be $6 \times 210 \times 4 = 5,040$ cubic feet, so that in three years' time, with the assumed proportion of silt clearance, the drain-work would amount to 20,160 cubic feet, or within 4 per cent. of the cost of the terracing. On the other hand, with a 1 in 3 or 18° slope in the ground, the quantity of earthwork to be paid for in terracing an acre would be $50 \times 210 \times \frac{2}{3} = 7,000$ cubic feet, while to cut drains in it the quantity of earthwork would be $6 \times 210 \times 2\frac{2}{3} = 3,360$ cubic feet, so that, with the assumed amount of silt clearance, the cost of the drains would, in only two years' time, exceed that of the terracing by nearly 44 per cent.!!

In regard to the assumed proportion of silt clearance, it may be noted that, assuming four clearances during the year, it gives an average depth of about three and-a-quarter inches for each; and that even if the quantity of each clearance does not reach the assumed proportion, the annual cost of all of them does so.

It will thus be seen that in all lands the cost of terracing is equalled, if not exceeded, by that of drain-cutting in about three years' time, while in the flatter or more gently sloping lands the difference is made up practically in a single year.

With regard to the depths of Darjeeling and South Indian soils, if there is any deficiency on plantations in the latter, it is not to be wondered at when the estates are weeded bare and soft, and are exposed to an annual depth of about fifteen feet of water acting under the best possible conditions for promoting denudation!

PEERMAAD,
26th December, 1897. } H. W. P.

[Criticism of the above letter is invited. The last para. does not touch the point of the respective depths of soil on jungle land in Darjeeling and South India.—ED.]

GENERAL ARTICLES.

SOIL RENOVATION.

ONE often hears it stated as a reason that old coffee does not bear as well as it used to formerly that the soil is exhausted. Now, however true this may be as regards the capacity of the coffee to extract nutriment from the soil, it is certainly incorrect to speak of the soil being exhausted itself. This is clearly proved by the fact of the annual growth of jungle and weeds on an acre of abandoned coffee must contain many times the nitrogen and minerals removed by a coffee crop. Tea is a far more exhausting crop than coffee, and grows freely in land that coffee can no longer exist in, so that rather than speak of the soil as being exhausted, it would be more correct to say that the supply of plant food in suitable combinations for coffee to attack is exhausted. Land left to itself uncropped and uncultivated accumulates fertility. Nature works incessantly and laboriously on behalf of soil fertility; and in undertaking the renovation of coffee soils, I do not believe there is the slightest necessity to employ any other agents than those that nature employs; all that we have to do is to so direct their energies that they may be subservient to the end desired, *i.e.*, the creation of a permanently fertile coffee soil. Nature herself has given us a very good standard of a fertile coffee soil in the form of new clearings from the forest. That there is ample plant food in new clearings is shown by the vigorous growth of the coffee plants, and a moment's consideration will show the great difference there is between new clearings and land that has been opened only a short time. To begin with, wash has not played havoc with the surface soil. There is a very large amount of organic matter in the form of roots left in the ground which run deep in every direction which tend to the complete aeration of the soil. The surface is covered with the worm-casts and the worm burrows honeycomb the land, all tending to the complete drainage and aeration of the land and destruction of wash. The disappearance of worms and the decay of the roots leads to a great consolidation of the soil, and the absence of the previously existing aeration must be fatal to the millions of microbes on whose efforts we are told soil fertility so largely depends; while the disappearance of the jungle gives that most deadly enemy of coffee, wash, a fine opportunity. Nature is at one with me in agreeing as to the damaging effects of wash for the first thing she does in taking in hand abandoned land, is to promptly put a stop to wash. That wash is to be feared I don't believe, given enough shade and thick coffee under it; at any rate I believe that wash from a coffee clearing can be practically reduced to the wash from the jungle, and that wash we know is not inconsistent with the accumulation of fertility; the aeration of the soil by the original jungle tree roots can be more or less replaced by the shade tree roots, and if the earthworms can only be induced to resume their labours, then we have practically got the soil of the coffee clearing in the same condition we have received it from nature, and by substituting leguminous shade for the ordinary jungle, we have possessed ourselves of an unlimited gratuitous supply of nitrogen, which is undoubtedly of the greatest use in combating leaf disease. The important part earthworms play in the renovation of soil and maintenance of fertility is not generally fully appreciated. Last year in September, *P.O.* gave an extract from Darwin, to which I must refer your readers, who are in want of full information of the subject, and will content myself with remarking that Darwin compares the action of earthworms to that of ploughing, and that, in a few years, they effect a complete inversion of the surface soil. Worms only thrive where there is plenty of organic matter. Their diet consists of half-decayed leaves, and organic matter which is ground up in their gizzards with the aid of small stones. A worm internally, I may remark, is geared on the same system as a fowl; only what is usually called a crop in a fowl is called by courtesy a stomach in worms, and both worms and fowls rejoice in the possession of gizzards. Prof. Scott says of worms: "Their action as soil-fertilizers consists in swallowing earth, leaves, and organic matter of all kinds, saturating it, converting it, and then ejecting it over the surface of the field. In this way they very soon effect a complete inversion of the soil down to a certain depth, especially on meadow land, which is left undisturbed to their operations. They even make additions to the soil by bringing up fresh matter from the sub-soil. Every time a worm is driven by dry weather or any other cause to descend deep, it brings to the surface, when it empties the contents of its body, a few particles of fresh earth. At the same time it fertilizes the sub-soil by opening up passages which encourage the roots of plants to penetrate deeper, these passages being lined with excreted matter which provides a store of nourishment for the roots. On meadow land, Darwin found these worm-casts amount annually to 18 tons per acre, and on good arable land to about ten tons. Dr. Gilbert has analysed worm-casts and found them to contain ·34 nitrogen, which is several times more than is found in ordinary soils. Ten tons of these worm-casts will thus yield 80 lb. nitrogen, or as much as is contained in two acres of a wheat crop." This is, of course, only in reference to worms and their work in England, and the point might fairly be raised is the output in quantity or quality in India equal to it. I have no hesitation in answering yes, and under favourable circumstances considerably in excess. To begin with the quantity or weight by acre. Every one is aware of the enormous size of the worm-casts in the jungle compared with the worm-casts at home. In "Forestry in Southern India" by Major-General Morgan, the amount of worm-casts is estimated at an annual deposit of two inches in depth per acre. This I can well believe when it is considered that many individual castings are over 4 inches high. Now two inches depth would be equal to about 80,000 lb. of soil per acre per annum. This conclusively

Soil exhaustion, a misnomer.

Nature and wash.

Worms at work.

Worms in England.

Worms in the East.

answers the query as to quantity available, and before I answer the point as to quality, it may not be out of place to point out that the quantity of worm-casts to be had depends largely on the kind of tree they are under. Among other trees, lime and shoe flower seem to promote the activity of worms to an unusual extent. It was the extraordinary amount of worm-casts under the *Erythrina Lithosperma* coffee, an amount actually in excess of the casts in virgin forest adjoining, and the also undoubted connection there seemed to be between the amount of casts and the vigour of the coffee: the more the castings, the more flourishing the coffee, that led to an inquiry into the constituents of worm-castings, and they gave an analysis results that may be fairly called startling, showing what an enormous complete source of fertility they are in themselves. At the same time an analysis was made of the finest portion of the soil from a few coffee trees under rock trees that bore a heavy maiden crop and bore heavily ever since. The soil was the finest portion only so as to get a fair comparison with the fine soil of the worm-casts. I give the two analyses:—

Ideal Coffee Soil.

Lime (Ca O) p. c.		...	1·792
Phosphoric acid ($P_2 O_5$) p.c.		...	4·473
Potash ($K_2 O$) p.c.		...	·910
Nitrogen (N) p.c.		...	1·260

Worm Castings under E. Lithosperma Trees.

Lime	(Ca O) p.c.	...	2·240
Phosphoric Acid	($P_2 O_5$) p.c.	...	5·112
Potash	($K_2 O$) p.c.	...	1·017
Nitrogen	(N) p.c.	...	·840

I may add that the worm-casts were taken fresh from different parts of the field to get a representative sample, care being taken to take them from under the oldest E. L. trees, so that the beneficial effect of the shade tree might be fully demonstrated and that the land they were taken from was unmanured, or to be strictly correct, was manured seven years ago with cocoanut poonac, so I am quite justified in describing it as unmanured. Both the analyses show soils of marvellous richness. The soil I have described as ideal coffee soil shows an enormous amount of phosphoric acid, and a phenomenal quantity of nitrogen, thus affording direct confirmation of the benefit of fish as a coffee manure. The analysis of the worm-casting is even the most remarkable, and is, I believe, the first that has been made with a view of showing the improvement in soil effected by leguminous shade. Legumes and earth-worms are, I believe, nature's two greatest agents in renovating soil. We see from the analysis that their allied forces form a perfectly irresistible combination on behalf of soil fertility.

We have the surface soil converted into humus containing one-half times as much nitrogen as cattle manure and infinitely more mineral constituents.

We have reckoning on a very safe basis of a supply of one-inch depth only, or reckoning the worms' outturn of work at only Darwin's estimate of their work in meadow land in England, 18 tons per acre, or, say, 40,000 lb. per acre, an annual supply of plant food as follows:—

Supplied by Legumes and Earth-worms.

Nature on the job.

2044 lb. Phosphoric acid.
896 „ Lime.
404 „ Potash.
336 „ Nitrogen.

against a crop removal of a few pounds of the same constituents. Surely after supplying the wants of the coffee trees, there must be an enormous balance to be carried to the credit of the enhancement of *soil renovation*. Whether nitrogen has attained its maximum is doubtful; I think it probable that with the increasing age of the shade trees that there will be further increase in the soil. It is, of course, impossible to say what proportion of the minerals shown in the worm-casts has been derived from the decaying matter of the shade tree loppings and sheddings, and how much has been elaborated by the worms from the soil, but of the value of everything in the form of worm-casts there cannot be any doubt, only the finest soil being selected by the worms and intimately mixed with the organic matter, the result being, as Darwin says, worm-casts are prepared as a gardener prepares soil for his choicest plants. Taking the analysis of worm-casts, it is very evident that cattle-dung could not be profitably used with them; cattle dung could only depreciate their v
So far I have only dealt with the value of the worm-castings the very important action of worms in draining and aerating th is well worth taking into consideration in considering their ut By themselves, provided their activity is stimulated to the ut they are capable of maintaining the soil in a high state of cul tion. With their combined properties of aerating, draining mulching the soil, worms are no doubt an auxiliary labour whose efforts on behalf of soil fertility are well worthy of stimula

An economical labour force.

and they have an advantage over coolie that they work their hardest without being quite satisfied with working for t grub, and at the same time it is possible to direct their energie given spots; for where organic decaying matter is, there will worms be gathered together, so to get the maximum amount of v out of our automatic cultivators, all we have to do is to pile the lopp and thinnings of the shade trees round the coffee trees, and by means we can concentrate their efforts in the desired direction. interesting point in leguminous manuring is that of the value of nitrogen in legumes. As different nitrogen compounds have s different values attached to them, an authoritative statement a the value of nitrogen in legumes will, I am sure, be welcomed extract the following from the Imperial Institute Journal wh appears in the *Indian Forester* for September. It is from address delivered by Prof. Maercker, of Halle, delivered to German Chemical Society in the current year summarising advances made in agricultural chemistry during the last twenty- years. The relative value of nitrogen compounds for plant foo given as under:—

Nitrogen of saltpetre	...	...	... 100
„ of ammonia	...	...	... 85—90
„ of albumen	...	...	... 60

and in reference to legumes: "The recognition of the powe leguminous plants to act as nitrogen collectors is manifestly of g practical importance, for it shows clearly that the best rotatio crops is one in which a leguminous crop is followed by one of nitro consumers, *i.e.*, plants which cannot assimilate nitrogen direc Leguminous plants, whether first used for fodder for animals simply left in the soil to decay, have their albumen changed in first instance to amides, which under the influence of ammo ferments are decomposed with formation of ammonium-carbon The salpetre bacillus then converts the ammonium-carbonate (probably also amides) into saltpetre, *i.e.*, the best form of plant food." Saltpetre is another name for nitrate of potash, so tha growing and manuring with legumes we are manuring with nitra The quotation I have just given clearly proves that we can grow own nitrates and will, I hope, set at rest once and for all any ques as to the value of leguminous manuring, and having established manuring with legumes is manuring with nitrates, I don't know there is anything more to prove to convince anybody of the v and efficacy of leguminous manuring. Coffee, if there is any relia to be placed on analyses, is surely a crop that ought to be speci benefited by nitrate of potash. Potash is the only ash constituent is removed, save in insignificant proportions, and nitrogen is largely required, especially to combat the drain of leaf disease, so leguminous manuring seems especially suitable for coffee, and am legumes it would be difficult to find one in which nitrogen and po enter so largely into its composition as they do in the case of *E. l sperma*. The outlook for coffee is none too cheery at present, with falling markets, enormous Brazil crops, and a "token" rency, with no possibility of reducing the cost of cultivation, so

Legumes equal nitrates.

Generosity of Nature.

announcement that Nature has provided with an unlimited supply of the most co nitrate—Nitrate of Potash—may fairly welcomed as the silver lining to the cloud. The close connec between Science and Practice is well illustrated by Science—C Cultivation without Manure. The enormous power suitable l minous shade has of enriching the land in nitrogen is cle demonstrated by the analysis of worm-casts, and the valu legumes is further emphasised by their conversion into nitrat potash, and most assuredly the 3 lb. per annum or so of lime phosphoric acid required for a 7-cwt. an acre crop of parchment

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

e supplied over and over again as long as the shade trees grow, or he earthworms are at work. I had intended to have gone into he question of the best way of making the most use of the shade, n order to derive the greatest benefit from shade and the greatest ield from the coffee: only the fear that I have already trespassed oo much alike the space in *P. O.*, and the patience of your readers, nduces me to reserve discussing that most interesting question for future opportunity.

B. NELSON.

ANISE.

AMONG the numerous by-products of the Assam jungles are those ossessing essential oils, says a writer in the *Indian Planters' Gazette*, ut with tea pervading most minds these plants have hitherto eceived little attention. Anise or, as it is better known, anisette, he *Pimpinella an sum* of botanists, is found in all the forests, but most abundant on the low *teellahs* under the hills. Being chiefly, ome upon under dense shade, the Assam plant is dwarfed; but when emoved to the open, and liberally treated in the way of cultivation nd manure, rapidly responds. Though a jungle production, it is a elicate plant to move, as the tendrils of the root are exceedingly elicate, so that when transplanting as much earth as will guard he rootlets from contact with the atmosphere should be lifted. Open pruning-out to be adopted, and if labour is available, exposing he surface roots *when once the plant is established*, should be resorted o, for, like the rest of the order to which anise belongs, the *Calyci-lorœ* is a perfect glutton, as far as manure is concerned. Although he indigenous anise would presumedly turn out profitable enough o propagate as it is, seed of the Chinese variety from Macao would go a great way to improve it, and we would recommend hybridisation, ither by grafting, budding or impregnation with pollen from the mported plant. The different varieties of the *Calyciflorœ* are too umerous to mention in detail, but for the extraction of essential oils some being used for medicinal and culinary purposes, or the basis f liquors), these consist of anise, carraway (*carumcarin*), dill *onethum graveolens*), coriander (*coriandum sativum*), cummin (*cum-ninuno cyminimo*) and others that will no doubt suggest themselves o our readers; *hydrocotiyle asiatica*, which is reputed as an arrester f, or palliative for, leprosy also belongs to this order, as also *conium naccelatum*, the well-known common hemlock and similar allied plants many of which have fallen into disuse; the once belauded scent opoponax, distilled from the resin of *opastinaca* and *chironum*, are of he same family.

UTILISATION OF BONE-DUST MANURE.

THE following are the contents of No. 15 of the *Agricul-ural Ledger*:—

As regards (1) Utilisation of bone manure, it was mentioned in the eports of 1893-94 and 1894-95 that no further experiments had been nade in the province with bone-dust manure. The mill for crushing ones, started some years ago by Mr. Drummond, Deputy Com-nissioner, Karnal, in the Kunjpura estate, has been given up on the round of expense and absence of demand for the bone manure, and he mill, started at Lahore by the late Mr. Robson, for crushing bones or export was closed some years ago on his death. Even when the nill was working, there was no demand for the bone-dust locally for nanure. The price (about Rs.1-2-0 per maund at Lahore) was onsidered prohibitive by local agriculturists not accustomed to ntensive farming, though farmers in England are willing to pay £5 o £6 per ton, say Rs.3-4 per maund for the bone-dust as manure.

I am afraid that, while bone-dust manure is so costly according to ative ideas, and so long as the prejudice against its employment ontinues, especially among Hindu agriculturists, little can be done o check the exploitation of this valuable fertilising agency. It has, owever, to be borne in mind that Indian soils are deficient rather n nitrogenous matters than in the phosphates which bone-dust is o rich in, and bone-dust manure, which is so highly appreciated in Europe and America, has not been proved by experiment to produce qually good results in this country.

The exports of bones from Karachi, which come mainly from the Panjab, is meanwhile increasing with extraordinary rapidity, as the ollowing figures prove:—

	Exports in cwts.
1892	186,500
1893	227,133
1894	338,691
1895	422,582
1896	493,844
1897 (up to 26th May)	271,286 (in five months).

No doubt it has been stimulated within the last two years by the great losses of cattle in this province from drought and starvation. The price at Karachi remains from at Rs.1-1[illegible] to Rs.1-12 per maund (84 lb.) of dry uncrushed bones, and this year the value of the bone exported up to date is considerably greater than that of all food-grains exported.

[The above note will be read with interest, as it draws attention to the fact that such a useful fertiliser as bone-dust is readily obtainable from an abundance of raw material which can be easily disintegrated in this country. That there is a desire on the part of planters to possess themselves of this manure at a cheap rate was shown by the United Planters' Association of Southern India recently petitioning Government with a view to impose an export duty on bones. The bone meal manufactured in India is remarkably pure, and compares very favourably with that sold in England. The first of the two analyses quoted below is that of a genuine sample of bone-dust made by Mr. F. J. Lloyd, F.C.S., of London; the second is an analysis made by Mr. D. Hooper of bones crushed at Coimbatore, Madras Presidency:—

	1	2
Water	9·90	7·30
* Organic matter	33·70	28·70

	100	100
* Containing nitrogen	3·66	3·32
Equal to ammonia	4·44	4·03

PINEAPPLE FIBRE.

THE United States Department of Agriculture has recently communicated a special report on the subject of pineapple fibre. As the pineapple is now largely cultivated in Assam, and has become naturalised in India, the information contained in the report should have considerable interest to pineapple-growers in this country.

In preparing the fibre, the green leaves are steeped in water for some days, as they become unmanageable if allowed to dry. The native method of hand preparation is to lay the leaf upon a board and remove the epidermis and succulent matter with any suitable scraper. A two-handed bamboo plane is used in China, while in the Philippine Islands the blunt end of a potsherd is employed. When the epidermis has been removed, the fibres are exposed, running in a longitudinal direction. Another worker now takes the planed leaves, and loosens with his thumb nail the fibres near the middle of the leaf and, gathering them in his hand, detaches them from the outer skin. The fibre is very fine and soft, the filaments being quite flexible and resistant; they yield readily to treatment in an alkaline bath, and are easily subdivided. After separating from the skin, the fibre is steeped in water, washed, and laid out to bleach on wide frames of split bamboo. The processes of washing and exposure to the sun are continued until the fibre is considered to be properly bleached. The isolated fibres are now very fine, and of a tolerably regular diameter, although varying considerably in size, the interior canal being very noticeable in the larger, but almost absent in the smaller, ones. The points are rarely sharp, but generally rounded.

It is claimed for pineapple fibre that constant immersion in water does not in the least injure it, and the natives tan it, with a view of increasing this property, though this is probably done at the expense of some of its strength. The fibres are very flexible, curling and twisting readily. Although naturally fine, the bleaching process, which destroys the adhesion between the bundles of fibres, renders it so much finer that it can be spun like flax. Both the wild and cultivated pineapple yield fibres which, when spun, surpass in strength, firmness and lustre those obtained from flax.

For the manufacture of sewing thread, twist, curtains, etc., its particular qualities render it specially applicable.

In tests of strength, pineapple fibre exhibited superior tenacity. The fibre from Singapore bore a strain of 350 lb., as against 250 lb. borne by New Zealand flax. This latter is considered superior to the

highest grades of English hemp. In the *Journal of the Agricultural Society of India* (Vol. III., p. 182), there is a record of a rope of pineapple fibre, $3\frac{1}{4}$ inches in circumference, bearing a strain of 5,700 lb. before breaking.

In the East Indies, where the pineapple was introduced as early as 1600, the fibre is exclusively employed in the manufacture of the delicate fibre known as "pina" as well as for cordage. "Pina" is considered more delicate in texture than any other product manufactured from vegetable fibre. It is woven from untwisted fibres, after they have been reduced to extreme fineness, and have had the ends glued together to form a continuous thread. The plant is specially grown in the Philippines, and it is customary to remove the fruit before maturity, so that the leaves may be more fully developed. Were the industry to be established commercially, it is certain that the tedious process of hand preparation would be superseded by machinery. Several machines have been invented, and Spon describes one by Sanford and Mallory, which cleans, it is stated, from 6,000 to 8,000 leaves per day.

The machine used by Mr. Dodge, the author of the United States' Report, was one by Van Buren, which, while turning out a superb product, would be quite inadequate for the work from a commercial standpoint, as only two or three leaves can be fed in at a time. The Florida fibre, when simply plunged into cold water for a few moments after coming from the machine, and then dried in the sun, came out almost white, and of a fineness and softness unequalled by any other leaf fibre with which the department had dealt.

Quotations as to value are not at present available, as the fibre is not yet a commercial product. There seems no doubt that if the fibre could be produced in quantity, at economical cost, manufacturers would readily find use for it. The question as to a suitable machine, enters largely into the problem. Estimating ten leaves to a pound, there would be over 22,000 leaves to the ton, from which about 50 to 60 lb. of fibre is obtainable. The Sanford and Mallory machine; capable of clearing 5,000 to 8,000 leaves a day, would only produce 12 to 18 lb. of fire; this would make it somewhat high in price. The United States Department of Agriculture intends to carry its experiment with pineapple fibre further, so as to give manufacturers opportunity of examining it. It may beadded that the value of Indian pineapple fibre is being ascertained, and its characteristics investigated in the Scientific Department of the Imperial Institute.

JADOO LIMITED.

Capital £50,000 in £1 Shares.

The Directors are open to receive applications for shares to a limited amount at a premium of 5*s.* per share, which premiums will be carried to a reserve fund and separately invested. Application should be made to the Secretary, Palace Gate, Exeter, accompanied by a remittance of 7*s.* 6*d.* per share, being the premium of 5*s.* and 2*s.* 6*d.* on account of the shares. Forms of application can be obtained from Messrs. Parry & Co., Madras, or Messrs. Octavius Steel & Co., Calcutta.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 21st January, 1898.

South Travancor SHENCOTTAH.—What coffee there is continues to look well, but we are not having our usual winds. No wind generally means working up for rain, and this is anything but wanted for another month.

Coorg. POLLI BETTA, 11*th January.*—*Weather.*—The weather has continued severely fine for the past fortnight. East wind has been rather strong. *Crops.*—We are rapidly nearing the beginning of the end of crop. Picking and stripping going on. Pruning commenced. *Plant Diseases.*—Leaf-disease has disappeared, and trees are coming nicely out of the pruning. Prospects for the coming season are very good. *Public Health.*—A lot of fever and bowel-complaints prevalent. *Interesting Item.*—Chief Commissioner to visit place on 17th instant.

Lower Pulneys. *5th January.*—*Weather.*—Cloudy on 29th, 30th and 31st December 1897, with light falls of rain on west and south of these hills. Since 1st January it has been clear, days are now hot, and nights very cold, with heavy dews. The N.-E. monsoon of 1897 has been a failure. *Crops.*—Coffee coming in slowly. Grain getting expensive. *Labour.*—Sufficient. *Health.*—Generally good. *General.*—Estates are working remarkably well. Leaf disease in a mild form on a few places. Green bug still with us, especially in the south, this scale pest begins to show up badly after April.

Nilgiris. COONOOR. — 12*th January.* — Weather bright, cold and unclouded till yesterday, when thick mist and a strong wind rose. A score this for the "moonists"! Crops not more than half in yet on most places, quality of bean good. Lots of good wood, as per usual, for next year. The failure of the N.-E. monsoon leads us to expect anything but seasonable weather, though, this year. Tea flushing unusually well for this time of the year, as the frosts have been very slight so far. Pruning in full swing.

No interesting news to relate, not even items. Excepting that the "great" Nilgiri Plantations Company are not likely to be exactly in clover this year, as far as crops go. Grand effect the Company has had in raising prices of local estates: every one wants "company prices" now.

Grain rates still high, health of coolies fair. Labour abundant.

AGRICULTURAL CHEMISTRY.

A QUARTER OF A CENTURY'S PROGRESS.

THE last twenty-five years of agricultural research have witnessed momentous changes, and none more complete perhaps than the now general recognition of chemistry alone being unable to grapple with the practical side of agriculture. In an important address delivered towards the close of last year by the celebrated Professor Maercker, of Halle, to the German Chemical Society, a lucid review is given of the progress of Agricultural Chemistry. Analytical Chemistry, *pur et simple*, no longer holds the commanding position it did. On the contrary, the Agricultural Chemist is now often more concerned with the biological sciences than with chemistry. The three most important divisions of latter-day agricultural research are Plant Food, Soils and Manures, and lastly, Artificial Selection.

PLANT FOOD.

Until the quite recent introduction of water and sand cultures, very little was known of the forms and quantities of the nourishment required by plants. By means of these cultures, from which all extraneous influences are rigidly excluded, we can trace the action of many substances in the plant itself. Thus we know that nitrogenous substances in the plants cannot be formed without the aid of phosphoric acid, for the albumens, which are of such transcedental importance in the transformation of substances in plants, result from an intermediate phosphoric acid compound. Again, iron is an essential constituent of chlorophyll, as sulphur is of albumen. The true action of calcium was long doubted. It is now known to be of a medicinal character, serving to neutralize the poisonous oxalic acid, which is always an intermediate product of the carbo-hydrates. Potash again has the closest of relationship with the formation of sugar in beets. Magnesium appears to be of importance in the formation of nitrogenous compounds in seeds, while nitrogen is of course indispensable, being an essential constituent of albumen.

Wolff has conducted some curious experiments, proving what he calls the "*mineral hunger*" of the plant. In other words, though a certain minimum amount of minerals may suffice to induce a healthy growth, all plants grown under normal conditions contain a great excess of this minimum. Oat-plants for instance require for their healthy growth the following minimum amounts of important minerals:—

Phosphoric acid	·50	parts.
Potash	·80	„
Lime	·25	„
Magnesia	·20	„
Sulphuric acid	·20	„
	1·95	„

But no oat-plant in nature contains under 3 per cent. of minerals. The difference, 1·05 represents the mineral hunger of the plant, such excess of mineral not performing any special function. As it might well be applied in the form of an indifferent substance like silica, it shows that it is not economical to manure crops with pure substances.

SOILS AND MANURES.

Knowing what the plant requires as food, the problem to be now solved is how to apply it in the soil itself. Unless accompanied by a "mechanical analysis," meanin chiefly a determination of the amount of finely divide constituents in the soil, it has been found the chemic analysis of a soil is of little use as a guide. It is only t finely divided earth which presents a sufficiently lar surface for the exercise of the solvent action of water a its dissolved carbonic acid. Where only traces of important plant-food are found, there is of course question as to the advisability of supplying that constituen

On the other hand nitrogen for instance may be reveale in great quantities by analysis, yet plants growing on suc soil may require liberal doses of that element to enab them to thrive. For in the form of humus or mould, very large proportion of the nitrogen is quite unavailab as plant-food.

Phosphoric acid affords another illustration. Whe applied in a soluble form it is of course available to t plant, but in time may change into insoluble tricalciu phosphate, or even to iron or aluminum phosphates, whic are still less soluble.

Calcium or lime however may be easily determined b analysis, since it is chiefly valuable in the soil as carbona or humate, and these are easily estimated in the soil.

Direct analysis being then a failure, attention has bee turned, and with great success, to the indirect or cultiv tion method, in other words letting the plants themselv determine the quality of the soil. Most of our readers a probably well-acquainted with this method, common known as Ville's test-plots. A sufficiency of each an every constituent of plant-food is given, save one. Th plants are then analysed and compared with plants grow on soil containing the complete plant-food, and one impor ant result of this method has shown that different plan take up very different quantities of the same mineral sub stances. The system of rotation of crops is based on th fact.

By means of the cultivation method a very useful tab has been drawn up showing the relative value of th different nitrogen compounds as plant food:—

Nitrogen in saltpetre (nitrate of potash) ...	100
„ „ ammonia	85 to 90
„ „ albumen	60

These test plots may also be used for testing the valu of manures of all kinds, as in the case of "Thomas" sla which is now used to an enormous extent as a phosphat manure. Similar experiments with regard to potass manures have given a great impetus to the potash industr The "cultivation method" of analysis has given us almo control of the fertility of a soil, as far as this depends o manuring. It has taught us amongst other things tha sandy soil, so long considered almost barren, can be mad extremely fertile by the scientific addition of manures.

A last point, and one to be well borne in mind by th unscientific rule-of-thumb planter, is that the supply excessive nourishment is a disadvantage and only tends t produce sick plants.

ARTIFICIAL SELECTION.

This last branch of agricultural research is one of enormou importance, though still in its nearest infancy. By its ai the fertility of plants may be increased far beyond th limit which Nature appears to have fixed. German agricu ture would long since have broken down under the stres

of foreign competition had it not been for the perfect technology of its agriculturists. The very success achieved spurs them on to greater efforts. We Planters, who, as a class, are so woefully behind the times, have never tried to perfect our technology in a scientific way. And it seems as if the day of our first united efforts were still far distant.

To return to artificial selection. The case of the fight of the sugar-beet against cane sugar affords a splendid instance of the triumph of scientific agriculture over rule-of-thumb methods, though aided by cheap tropical labour. Originally the sugar-beet contained only a small proportion of sugar, and could only be used for sugar manufacture when the price of cane sugar was very high. We will quote here the words of the *Imperial Institute Journal*: "With the fall in price came the urgent need for increasing the percentage of sugar in the beet-root. This was effected by utilising the fact that sugar richness is hereditary, so that by selecting artificially the roots richest in sugar, getting seed from these, planting the seed, again selecting the richest roots and so on, a race of plants is at length obtained in which a high percentage of sugar is normal." The beet industry now supports great laboratories for carefully determining the percentage of sugar. By these and other efforts sugar is cheaper now in Germany than flour, costing less than a penny a pound.

What is this but the methods we have so persistently advocated in improving our coffee-strains? Yet, because Planters as a class are so utterly unfamiliar with the methods of scientific agriculture, they look upon such questions as impracticable. They are impatient of delay, results that cannot be obtained in a year or two, are not, so they opine, worth obtaining at all.

Success similar to that obtained in the sugar-beet has also been attained in the different crops of grains, malt-barley being a special case in point.

Highly-cultivated and artificially selected plants easily lose their acquired characters when exposed to unfavourable conditions. This has led to a series of exact investigations, the most interesting being the tracing of the history of nitrogen as it passes from the atmosphere to the soil, then into the substance of plants, and finally into the atmosphere.

As a rule plants can only assimilate nitrogen in the form of compounds. But the supply of these compounds in the atmosphere is comparatively small. There must be some other source of supply. This is the order of leguminosæ or nitrogen-collectors, which are able to assimilate elementary nitrogen, and so enrich a soil in which they have been grown, with nitrogen compounds. This power of collecting free nitrogen has been always associated with the presence of micro-organisms in the roots.

Mr. Nelson's áble articles on this subject have rendered most of our readers familiar with this side of agricultural research. An interesting point, however, which we do not remember seeing before, is the conversion of the nitrogen of legumes to saltpetre when decayed in the soil. We have given this point in a paragraph in our "Notes," to attract general attention.

Unfortunately, the whole of the nitrates thus produced cannot be taken up by plants on account of the destructive action of the nitrate-destroying bacilli (full mention of which has already been made in this Journal which decompose the nitrates and set free the nitrogen, which passes again into the air.

These nitrate-destroyers are usually present in stable manure and cause a loss of many millions of pounds annually to German agriculture. Efforts, which it is believed will result in early success, are now being made to avoid this loss.

* * *

With even this brief review before him of the progress of agricultural science during the past quarter of a century, can the reader seriously affirm that scientific agriculture is useless, that it is not worth spending a few rupees on? We in South India have only two staples, coffee and tea. Both are fighting their way exposed to the fierce competition from other countries. If we lag behindhand in the struggle, if we disdain to use the weapons lying at our command, we may be sure that our rivals will not be so apathetic. It is worse than useless to make light of the gravity of the struggle. Individuals, by the application of that foresight so deplorably lacking in the community at large, may weather the storm successfully. But individuals cannot hope to save an industry by their private efforts. It behoves us all to stand shoulder to shoulder, to join our resources and fight our way as a whole. We can easily help ourselves. If we fail to do so, the fault is ours and ours alone. Patent systems of curing leaf-disease and other ills our plants are heir to will not save us. In scientific agriculture and in that alone lies our salvation.

NOTES.

Flooding nurseries. The Editor of the Calcutta *Planter* gives a novel suggestion as to the best treatment of nurseries affected with disease: flood the nurseries and drown the pests!

Salt for agriculture. The possible uses of salt for agriculture being many and various, we are glad to note that the Ceylon Government has appointed a Committee to inquire into the best ways of denaturalising salt, presumably after the methods already in vogue in Prussia.

The Ceylon tea-crop. The revised estimate of the Ceylon Planters' Association for 1897 was 119 million pounds, the actual sailings show a shortage of very nearly 3 millions. The total shipments for the last three years were divided roughly as possible.

	1897. Million lbs.	1896. Million lbs.	1895. Million lbs.
United Kingdom ...	98½	nearly 94	85¾
Colonies ...	13½	„ 11¾	9⅓
Other Places ...	4	2½	2¾

A prosperous Company. The Ceylon Land and Produce Co., Limited, has a splendid record for the past eight years. Neither high exchange nor low prices seem to affect it. Steadily paying 6 per cent. to the preference shareholders, the ordinary shareholders have taken during the last eight years as follows, says a *Ceylon Times* writer:—

1890	...	10 per cent.	1894	...	15 per cent.
1891	...	10 „	1895	...	*15 „
1892	...	15 „	1896	...	*15 „
1893	...	*15 „	1897	...	*15 „

* And 5 per cent. bonus.

To kill trees. It is a matter of great difficulty to kill out certain trees, like the fig and eucalyptus tribe, that throw up suckers from their roots. As a general rule, a careful ringing, cutting well into the white wood, will effect the purpose, but this, we learn, is by no means invariably successful, as suckers shoot out below the cut. An authority on horticulture has informed us that a very good method of killing trees of obstinate vitality, is to bore holes well into the stem with augers, and fill up with caustic soda, giving each tree two or three ounces, according to size. The soda is very cheap and may be readily obtained anywhere.

Decaying Legumes form Nitrate of Potash. The following extract from an interesting article in the *Imperial Institute Journal*, on which we dwell at length elsewhere, will be of interest to many of our readers: "Leguminous plants, whether first used for fodder for animals or simply left to decay in the soil, have their albumen changed in the first instance to amides, which under the influence of ammonia ferments are decomposed with formation of ammonium carbonate. The saltpetre bacillus then converts the ammonium carbonate (and probably also amides) into saltpetre, *i.e.*, into the best form of nitrogen plant-food."

Average of Colombo Tea Prices. As given in the *Times of Ceylon*, the yearly average price for tea sold in Colombo since 1891 is as follows. In giving the quantities sold, fractions of a lac are omitted :—

1891	9,500,000 = 41 cents.	1895	19,600,000 = 47 cents.
1892	11,100,000 = 41 „	1896	25,400,000 = 41 „
1893	14,200,000 = 43 „	1897	26,500,000 = 37 „
1894	15,700,000 = 43 „		

A rapid drop since 1895, it will be observed, has taken place. At the present exchange 37 cents equals $5\frac{3}{4}d.$ and as the best tea usually goes home, and bearing in mind too the saving in freight, &c., the price compares well with London rates.

Coffee in Madagascar. The history of coffee in this island is a curious one. The industry was started in a large scale in 1871 by Mr. Alfred Guernot, in the Mahonoro district. A year or two later planting was undertaken throughout the island on an enormous scale, but such was the ignorance of the cultivators that after a few years all the plantations had disappeared, dying through absolute neglect and starvation. A single Planter, Mr. Jean Comte, now in Tamatave, was in the habit of yearly manuring his trees, which were cropping well till the late war broke out. In 1880 the local price of parchment was only 3 dollars per 100 lbs., now it is difficult to purchase it at 11 or 12 dollars. Nearly all the foreign community, by the way, drink tea in preference to coffee.

Experimental products. In concluding an interesting review of the year, the *Ceylon Times*, in touching on products other than tea, remarks :—

"The other older products do not call for much notice, except that the boom in the Cocoanut industry still continues, although prices have fallen considerably of late. Of the Cacao disease much cannot be said till the results of Mr. Carruthers' inquiry are known. The enterprise of this gentleman, and the Governor's desire to help Cacao planters in spite of official snubbing from Downing Stre and the apathy of the Kew Gardens authorities, are most commen able. We sincerely trust Mr. Carruthers will find a remedy for t Cacao pest. New products are being taken up with the decline tea profits. Rubber has already established itself and is plant over a large area in patches, and will undoubtedly prove remune tive to some. But the localities where it will grow to pay best a not known yet; and there is no doubt that some planters will suff loss by their experiments. The agitation over, Ramie fibre h died away to a great extent with the departure of Mr. Macdona from our shores. Small experiments, however, are still being ma and these will, we trust, lead to a further extension of the culti tion, which seems fairly promising over a considerable area Ceylon."

Early handling of coffee. Looking at the effects of ear and late handling, says an exchan correspondent, I have come to t conclusion that in order that the trees should derive t greatest benefit from the operation, the work should finished in August at the latest. I have noticed that whe the trees have been handled early the branches left on t trees for crop next season are fine and thick and hold o promise of bearing good big rings of berries at each of t nodes, but where the handling has been done late, the woo is more or less attenuated. This can be easily understoo In the latter case light has been excluded from the tre for a long time, and the sap has been diffused over a larg number of branches instead of being diverted into t requisite quantity for bearing crop. Another advantage early handling is that the wood and leaf left rapidly matu and are better able to withstand leaf disease. In ear handled trees, too, there is an almost constant growth young shoots which, I think, exercises a countervailin effect on the bad effects of leaf disease.

Venesta Tea Packages. Our local firms might do well import a few of these chests, judg ing from the following extract fro a Ceylon exchange :—

"We learn that the Ceylon Tea Plantations Company, after thorough trial of these boxes, are so satisfied with the results tha they have given orders that the whole of their 1898 crop is to b packed in this new form of chest. The trial lot on which the te was made contained nearly 100,000 lbs. of tea. The usual loss weight of tea on this would have been about 500 lbs. (exclusive draft) if ordinary country or momi packages had been used, but the Venestas were practically exact in weights there was a *gain* three pounds of tea on this large shipment. The teas were fro four different factories, so that the test was the more complet The packages arrived in splendid order, and were entirely satisfa tory. The Company, we are informed, expect to save some £1,00 per annum on their package account by the use of these chests. Th tea industry has waited many years for a perfect tea chest, and now seems that at last this has been found. We are informed tha the veneers of which these chests are made is manufactured i Russia, and only one firm holds the secret for the particular kind glue for fixing the veneers. The Chest Company tried Canadia veneers, and other sources of supply, but none were of any use fo box purposes. The wood used is birch, of which it is said the Russia Company has an unfailing source of supply."

The interests of Managers. Our worthy contemporary, th *Ceylon Observer*, has taken up th cause of the Managers and Superin tendents of estates, as far as relates to their being give a real share in the prosperity of the concerns whos interests they serve. The Editor, in noticing the ver natural objection Proprietors now feel in giving up an share of their contracting profits, pertinently remarks tha

it is probably only by such methods that the fall in the gains will be stopped. The tea-industry is by no means so flourishing as it used to be, the margin of profit is getting sensibly smaller. Every item of cost saved in the manufacture and preparation of the tea, every improvement in the field or factory, means additional profit to the proprietor. What inducement can be offered to the Manager and Superintendent, save that of sharing in the profits? For it is very certain that without some such additional inducement, the employés will not take the additional trouble inevitably required to render feasible the improvements noticed. Very sound advice, and most applicable, as we have already pointed out, to our own coffee and tea-industries.

Tea manuring and flavour.

The question of the use of manures affecting the flavour of tea has now reached a new phase. A Mr. Bour, of the Ceylon Manure Works, regards as a very great danger the increasing use of strong-smelling manures, such as raw bones, poonac and fish, on the novel ground of their directly affecting the flavour of tea by their objectionable odour. In proof of his contention, he remarks :—

"As regards the question of strong-smelling substances tainting the flavour of tea I would point out that I had been cautioned against their use by more than one authority on this matter, and as a practical demonstration one of the leading agronomists of France submitted to me samples of wine from a vineyard which had been manured with a strong-smelling fertiliser, and the flavour of which had been distinctly affected, whilst the wine from the unmanured plot of the same vineyard was all right. Further Mr. Hughes, on whose judgment must be placed the greatest value, expressing the opinion that no blood, raw bones and fish should be used as strong-smelling substances taint the flavour often, and that unless first treated with acid, these materials were dangerous, there being a risk that they might introduce some fungus disease which should certainly be a warning to planters considering the havoc done by the coffee leaf-disease. Mr. Hughes was very particular as to the ingredients to be used and that their composition should be such as to suit the nature of the soil, crop and climatic conditions of low-country and up-country estates. There will however be this further advantage that his mixture can be made up in any proportion which planters with practical experience on the subject, may deem best suited to the requirements of their soil."

Agricultural Chemistry.

Science takes a very, very long time to filter into the minds of agriculturists of all countries. It should surprise no one therefore to find that with perhaps two exceptions, no planting district of South India has thought fit to support the proposal brought forward last year at the U. P. A. meeting, calling for subscriptions to secure the services of an agricultural expert for our industry. In the proceedings of two District Associations reprinted in this issue, it will be noted that while Coorg thinks that private enterprise should pave the experimental way, the Nellampatty is of opinion that the whole scheme is useless. Ye gods and little fishes! Surely it is not difficult to see that, as regards the first objection, private enterprise must be infinitely more costly than combined effort, while not nearly so satisfactory. The Nellampatty decision is more difficult to argue with in a short paragraph. But as that cast of opinion seems common to most Planting Associations of South India, we must buckle to again, and do our utmost to do what we can to set forth the true value of scientific agriculture. Practical planting by rule of thumb has had a long trial in good sooth. With yearly falling crops and more virulent attacks of plant-diseases, can the good old rule of thumb be said to be a complete success? Or is it on the other hand, that the very failure of the old system has left no funds wherewith to try the new? Science, thy name is not "planting."

Coca growing.

It is a pity that more attention is not given to these valuable plants. At the ordinary coffee-elevation they grow very freely, and as the shade they give is exceedingly light and their development slow, they could be interplanted among the coffee without danger. The plant is really only a shrub of very sparse growth Fine specimens may be seen growing in the Burliar experimental garden :—

"Good coca leaves yield ·5 per cent. or more of cocaine, but the average is less, and if fermented often nil. The London market price of cocaine a few months back, was 9*s*. 3*d*. to 9*s*. 6*d*. per oz. Great care must be taken in the gathering, drying and preservation of coca, and its activity and value depend in a great measure on its mode of preparation. The leaves should be gathered as soon as they have arrived at maturity, at which period they are bright green on the upper surface, and yellowish green on their under surface, and have an agreeable and somewhat aromatic odour. The leaves are gathered separately and carefully by hand with the two-fold object of preventing them from being crushed or bruised in the process, and also so as not to injure the young leaf buds which are left behind for the purpose of obtaining a second crop of leaves. They are then spread out and dried slowly in the sun. The operation must be performed with great care, for if the leaves be dried too rapidly, they lose their odour and green colour; and if stored before they are thoroughly dried their colour is also changed, and they acquire a disagreeable odour and taste. Commercial coca either consists of the leaves more or less pressed together in compact masses or of the leaves in a loose state. In either case the leaves are not curved or rolled in any degree, but perfectly flat. The properties in the leaves are injured by transportation and often by keeping; they should therefore be packed in tin-lined cases."

LETTERS TO THE EDITOR.

RAMIE.

SIR,—The following facts with reference to "Ramie" may interest your readers. The letter is written by a Planter in Selangor, Straits :—

"Several clumps of ramie having an average of 20 stems each were cut down to within 3 inches of the ground on the 16th November last and the stools to-day (21 days from cutting) have an average of 40 stems, 3 feet to 3½ feet long and nearly ½ an inch in diameter; there are besides about 20 young shoots on each stool about 1 foot high.

"About 150 unrooted cuttings 6 inches high were planted on the 5th October last and in 28 days averaged 4 feet in height and are now all 5 feet and almost ready for cutting."

BANGALORE, *6th January*, 1898. ALOEKOP.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

DRAINS vs. DRAIN-CUTTING.

SIR,—It is easy to see that your correspondent "H. W. P." is no planter, for his calculations as to the respective cost of terracing and drainage are extraordinary to a degree. He would have done well had he taken the trouble to get some Peermaad planter (for he dates his letter from that well-known planting district) to give him the current rates for the two kinds of works he touches on. To reckon the cost of clearing out drains as being the same as cutting into hard subsoil to make terraces, is ridiculous

However, I will spare "H. W. P." any hard words, for it is not often that an outsider takes the trouble to interest himself in our industry. We should appreciate the compliment accordingly. In earnest, though, I think, that if a cheap and rational plan of terracing could be adopted, it would be to the very great advantage of all concerned.

Anyway, the more attention that is drawn to the subject of the great loss we all undoubtedly suffer from wash the better. If terracing cannot be managed, efficient drainage and other methods might effect the same purpose

But to return to our muttons. The six drains he mentions would cost about 7 rupees to 10 rupees, according to the slope, allowing a very moderate kanak per cooly. Cleaning out the drains would involve an annual cost of 2 rupees per acre at the outside, as the amount of silt deposited would be half the depth only of the drain.

Now for the cost of the terracing, which is not quite so simple. From a very limited experience I find it runs out from 30 to 50 ft. per acre. Taking the former figure as correct, the total initial cost of terracing is three times as great as that of draining. It would take *ten years* for the yearly outlay in cleaning out the drains to bring the two amounts equal.

So far as regards the money cost. Now for the practical side of the question. In our hot South Indian coffee-districts, the effects of long droughts are disastrous on the narrow style of terraces advocated by your correspondent. The coffee plant is a very shallow-rooted shrub. The greater the surface of soil exposed to the desiccating influences of sun and air, the more intense the danger of the plant dying out altogether in times of drought. This is no theory. It has been proved often, and disastrously enough in most districts.

The alternative is to have the terraces broader, say broad enough to receive two plants, in fact say ten feet. Now in the ordinary shallow South Indian coffee-district, this means that the inner half of the terrace will be merely subsoil, and will consequently suffer greatly.

If the field to be terraced is exceptionally rocky, it would be an excellent plan to merely build low retaining walls every row if possible. If not, the only alternative to my mind is to let terracing slide altogether and revert to shallow trenching between every row. Trenches, I mean, that would be continuous from one end of the field to the other, and would only be interrupted when cut across by the down drains. One foot in depth would be ample for the purpose, and as the first foot of soil is ever so much cheaper to dig than the second, the cost per acre runs out to very little. A cooly could dig 100 feet $\times$ 1 $\times$ 1 easily enough, I should say, as he can do $60 \times 1\frac{1}{2} \times 1$ without much urging. Roughly speaking, it would come out to about 17 feet per acre. Allow a single down drain per acre, at say 3 feet and the total comes to 20 feet.

Of absolute silt there would be almost nil, though the current works on estate would tend to fill them again every year. The cost of keeping them open must be considered in the light of the whole work of an estate, where cultivation is at all thoroughly carried out. For instance, if up and down trenching—mentioned by you in the last issue—be undertaken, no extra cost is involved at all; it becomes merely part of an alternative routine. Or otherwise, all prunings, weeds, loose stones, &c., should be placed below each trench to keep up the sides and deepen In this case it might be advisable to have more than down drain per acre; three or even four (shallow ones of cour would be good.

I am afraid I have rambled a good deal in this letter. the subject will bear a lot of discussion

The chief advantages I claim for my system is that, thou not so permanent as terracing, it is somewhat cheaper in initial cost; also that it will not tend to dry up the plants times of drought; finally that it can be applied witho difficulty to the oldest plantations now existing. 1 IN 2.

GENERAL ARTICLES.

UPPER BURMAH AS A PLANTING COUNTRY.

IN compliance with your suggestion, I send you a sho summary of my eight years in Burmah, regarding the gre advantages it holds out for the cultivation of coffee a tea.

When employed on the Burmah Ruby Mines I had oppo tunities of studying the rock, soil, and vegetation of th grand mountain tract.

The Forest Department divides the forests into t classes, the "Ever-green," ranging from 3,000 feet upwar and the lower zone, "Wintering" forest which sheds leaf as in Europe.

These forests are among the richest to be seen, timb and dense underwood clothing the mountains to the crests. "Tongmay," some 7,000 feet, is a mass of fore dominating all. To its northern side lies "Bernardmyo where troops are stationed. Southerly of this huge mounta range are "Mogôk" and "Kytpin" (pronounced Chopyn Where the ruby mining is carried on, the country connected by a metalled cart road to the river ghât Thebetkin, in all some 90 miles made for the sole use the Ruby Mines. The Irrawaddy Co.'s fine steamers touc here twice a week.

Coffee. This was found 15 feet high the forests, bearing a singular small berry. Like all wild species it is nearly all wood an leaf with but little fruit. It was found growing in war sheltered valleys and basins at 6,000 feet elevatio Hundreds of these trees I examined; no speck of le disease was there. Cultivation insects would improve th healthy variety. It was also found in scrub jungle 5,000 feet, with more berries on it.

Tea. An old Assam Planter showed m trees that I at first could not believ were tea, they were so large, as thick as a man's thigh, an of considerable height. He deemed them superior Manipori in Jât, and he ought to know, for he had been Assam twenty years. They were found in the Ever-gree forest between 3,000 and 6,000 feet.

Soil and rock formation. The basic rock is granitic wit up-shoots of trap, again cappe with decomposed gneissic roc over-lying also is the alabaster, a sulphate of lime. This the matrix of the ruby, &c. As coffee requires 20% lime marley land carrying a rich thick vegetation is simpl perfect for growing coffee. The timber is very large, i the higher ranges huge oak trees with the crabapple cherry, pear, laurel, Spanish chestnut, &c., with willow growing on the water channels of this amply watere

ountry. The luxuriant underwood reminded me of the Ouchterlony valley," as "*Nillah*" underwood stretches or acres. Tree fern also and a vast succulent growth which nly a Botanist could describe, thrive on the deep loam. The grass lands were deep in high grass: where grazing vas, it was fine and filled with a great variety of crocus, &c., on the stream sides was the fox glove, pink and white.

In the flats in winter there is frost and ice, which yearly prevent the oak saplings from growing. Rainfall—showers n April and May—good after ruin to ruby; rainfall from 90 to 80 inches. The road escarpments and mines show he great depth of soil on its gneissic crumbled rock. It vill be borne in mind that Upper Burmah is near the Tropic of Cancer, 23°. The winter gives the fair-skinned plump Shan and Burmese girls red cheeks, and makes the people hardy. This vast tract of forest and grass extends 200 miles north of Bhamo and south to the Pegu District ome 700 miles, its breadth extends to the Siam frontier, ll lying east of the Irrawaddy. The land is so fertile hat for the past 100 years no manure whatever has been pplied to paddy, which gives one crop yearly.

Land tenure. Having been consulted by Sir Alexander Mackenzie, the then Chief Commissioner, as to the best tenure of land which would nduce *bonâ fide* Planters and investors to take up land, he tenure is most favorable for coffee and tea Planters, axes only commencing after the fourth year.

Labour. Much misconception prevails outside Burmah on this point. Having been working eight years in the Province and recruiting abour from Mogôk to Rangoon, I can write with some experience. When on the Ruby Mines I went out toward he Chinese frontier, and on two expeditions brought in 800 men without giving any advances, recruiting the Minthas, a race half Chinese and half Shan, big heavy built fellows. Half of these were put on to the Trunk road which is metalled for carts: one branch goes to Bernardmyo, the other to Magôk, some 90 miles in all.

The late Major Kunhardt, R.E., some time head of the Company, an officer of immense experience, from Pathans to all the different races of the Deccan, said they were superior to any he had seen at pick, shovel and hoe. The officials on the Frontier said *the supply was practically limitless*; they told me that they would have liked to bring their families with them. There are blacksmiths, sawyers, wood-carvers, rock-drillers, revetting-builders, and excellent jungle men. A strong manager of labour can get plenty of work from them with kindness and a firm hand. Next come the Burmese, who, after ploughing and putting in their seed, are available for eight months in the year: clever jungle men, but do not like earth-work. 3rdly, the Shans, who are industrious and hard-working. 4th, next to the Mintha are the Kerins, a law-abiding, brave, simple-hearted race, who have not been taught earth-work. Many thousands of the above are available. No energetic recruiting is done, and no advances are required. There are no Europeans engaged in the planting industry, excepting some Catholic missionaries and Captain Pelly.

When in the Henzada P.W.D. Division, I had 2,500 men the first year, and 3,000 the following year begging for contract work at rates it would not pay a European to touch. About 15,000 of these Telugu men—big, docile, steady fellows, are settled in Burmah, beside 100,000 who go back in a year or two to their country, and return.

These facts will go to prove that labour of the best sort is *abundant* without giving big advances.

There is the Railway now going up beyond Mandalay, and a fine river service of steamers. The officials gladly help *bonâ fide Planters with capital*, and the climate is first rate for coffee and tea. It is so rich that the paddy fields never require any manure. The cow is looked on as unclean by the Burman. An old Brahmin race taken prisoners many years ago graze their cattle.

4½, Esplanade, Calcutta,
3rd January, 1898. E. A. Quarme.

PRESERVATION OF GRAIN FROM WEEVIL.

[Professor Church.]

The only cheap and perfect application for the prevention of the attacks of weevil upon corn and grains consists in the employment of bisulphide of carbon. The quantity required, provided the grain is kept in closed vessels, is very minute—not more than 1½ lb. to each ton of grain—so that 8*d*. is the cost of preserving a ton of wheat. The bisulphide leaves no disagreeable taste or smell behind, and the quality of the grain remains unimpaired. When bags are used, instead of the iron cylinders specially prepared for use in the bisulphide process, the protective influence of this chemical soon ceases and a fresh application of the bisulphide must be made. In either case the liquid is applied as follows. A ball of tow is tied to a stick of such a length that it can just be plunged into the middle of the vessel containing the grain. The tow receives the charge of bisulphide like a sponge, and is then *at once* plunged into the sack or cylinder and left there, the mouth being closed tightly. When necessary the stick may be withdrawn and the charge (1 oz. bisulphide to 100 lb. grain) renewed.

[F. W. Cabaniss.]

I have been trying for several years a number of experiments with the object of finding a cheap and simple method of preventing the ravages of this weevil. I think that I have found it in the use of naphthalene powder. My method of using the powder is here given for the benefit of the grain dealers of Burmah. It is best to place the naphthalene powder at the bottom of the bin or bulk of grain. To accomplish this take a bamboo, about 1½ inch in diameter and long enough to reach from the top to the bottom of the bulk of grain. Punch the joints out of the bamboo, so as to be able to pass a stick through from one end of the bamboo to the other. Have the stick made to fit the cavity in the bamboo. Pass the bamboo, with the stick in it, down through the bulk of grain from the top to the bottom. Withdraw the stick, and drop into the top of the bamboo about half a teaspoon of naphthalene powder. The bamboo can then be drawn out, as the naphthalene is safe at the bottom of the bulk of grain. If the bulks are large this should be done once to every ten feet square of the bulk. Repeat the application every 15 or 20 days as the powder evaporates.

The weevils that can leave the grain will do so, and those that cannot leave are killed by the odour of the naphthalene. I do not believe that naphthalene thus used can cause any injury whatever to grain. For seed purpose the germinating powers appear not to be affected in the least. For marketable grain the colour is not affected, and the odour will leave in a short time if fresh naphthalene is not applied to it. The quantity of powder used is infinitely small in proportion to the quantity of grain, and the powder is entirely destroyed by evaporation, so that for food purposes the effect is *nil*.

DISTRICT ASSOCIATIONS.

COORG.

PROCEEDINGS of a General Meeting of the Coorg Planters' Association held on Tuesday, 7th December, 1897, at the North Coorg Club, Mercara, at 2-30 P.M. PRESENT:—Messrs. H. F. DAVY, H. R. EAST, JAMES T. MORGAN, W. H. SPROTT, and H. M. MARTIN, *Visitor*. Mr. W. H. SPROTT *in the Chair*.

Exchange Question.—It was resolved that this Association do support the policy of the U. P. A. S. I.

Mercara Sanitary Board.—Read proceedings of meeting of the Board, and the action of the representative of this Association was approved.

Agricultural Chemist.—That for the present at any rate this Association is of opinion no funds should be allotted for the purpose; the results of private enterprise and experiment are necessary before further action is taken.

Fraserpett Bridge.—Mr. Davy again brought to notice the dangerous state of the approaches to Fraserpett Bridge and the perfunctory manner in which the barbed wire was fastened to a few posts on either side of the road. This subject was last brought to the notice of Government in October 1896, but apparently nothing has been done.

The Honorary Secretary wrote regretting his inability to attend, also that the exigencies of crop would prevent a large meeting so late in the year.

With a vote of thanks to the Chair.

H. G. PARSONS, *Hony. Secy.* W. H. SPROTT, *Chairman.*

NELLAMPATHY.

PROCEEDINGS of a Meeting held at Alexandra Bungalow, December 22nd, 1897. PRESENT:—Messrs. EVERINGTON, FENTON, C. HALL, W. MORRES and J. C. ABBOTT, *Honorary Secretary*. Mr. C. HALL *in the Chair*.

Roads.—Read letter from the Dewan with copy of letter addressed to him by the Acting Chief Engineer, also extracts from "Dewan's Proceedings," dated 19th September.

Resolved "That this Association regrets that the Cochin Government has abandoned its intention of constructing a cart road to this district, but hopes that the bridle-path proposed as an alternative will be taken in hand without delay and speedily completed."

Read letter from the Dewan giving the Association permission to erect (at its own expense) a foot bridge at the bottom of the old ghaut.

Hospital.—Read letter from the Resident, and the Honorary Secretary's reply stating that the Association was prepared to fulfil its share of the agreement, and that the Dewan had already been informed of this.

Read letter from the Dewan stating that the matter was pending before the Resident, to whom he had referred it for advice.

Leaf-disease.—Read letter from the Secretary, U. P. A. S. I., with copy of letter from Mr. E. Quarme, who claims to have a cure for leaf-disease.

The meeting agreed with the Chairman, U. P. A. S. I., that it should be left to individuals to make arrangements with Mr. Quarme if they desired to take up the system.

Re-opening of the Mints.—This question was postponed until the next meeting, when it is hoped that there will be a larger attendance.

Agricultural Chemist.—The Honorary Secretary stated that a list had been circulated but no subscriptions had been obtained, the general opinion being that no good was likely to accrue from employing an Agricultural Chemist.

Coffee Scale and Lady Birds.—Read letter from the Secre U. P. A. S. I., asking to what extent this Association w subscribe towards the purpose of introducing coccinellidæ in S. I The Honorary Secretary stated that only Rs. 40 had been colle so far, but it was hoped that more subscriptions would come in.

Central Rice Store.—Mr. Watts being unable to attend the m ing, this question was postponed. The Honorary Secretary requested to ask Mr. Watts to draw up a scheme for working rice store.

Committee.—The following members were elected:—C. E. Jones, P. W. E. Watts, R. Milne, A. Barnes and J. C. Abbott

A vote of thank to the Chair terminated proceedings.

C. HALL, *Chairman.* J. C. ABBOTT, *Hony.*

CENTRAL TRAVANCORE.

THE Annual General Meeting of this Association was hel the Penshurst Bungalow on Monday, the 3rd of January, w there were present:—

Messrs. F. M. Parker (*Chairman*), H. W. Baker, H. J. Bland L. Crawhall, R. H. Goldie, R. S. Imray, W. H. Lehay, N. Macgo Spurgin, C. H. Williams, J. Arnold, F. Bissett, R. W. Court R. W. Cole, Hickley, B. Laurie, Macgrath, H. J. Place, Hon. W Wilbraham, and A. E. Veale (*Hon. Secretary*).

The minutes of last meeting having been taken as read, Chairman called on the Hon. Secretary for his report for past year, which was as follows:—

"MR. CHAIRMAN AND GENTLEMEN,—

It is customary at this, the Annual General Meeting of the A ciation, for the Honorary Secretary to submit a Report of the ceedings of the Association for the past year; but as Mr. Acw on his resignation of office, at the last meeting, read you so full complete a report, it is unnecessary for me to do more than al to what has taken place since then.

Travancore Game Preservation Regulation.—This Act, w was first agitated for by us, three years ago, has now been pa after having been sent up to the Supreme Government three t before receiving sanction. It is gratifying to note that the r lation is almost a facsimile of the draft Act drawn up by Me Bensley, Dighton, Acworth and others, with the main exceptio the clause relating to licenses, the absence of which is much t regretted. Our thanks are due to Mr. Bensley for the time trouble he has spent in pushing the matter. Section IV. of the R lation confers on certain Government servants and others, who from time to time be appointed, power to enforce the Act. Dewan, however, I regret to say, does not deem it expedient to co such powers on private gentlemen, until some experience of working of the Act has been gained. I fear the usefulness of regulation will, in consequence, be minimised.

Kumili-Kuravanooth Ghat Bridge.—Ever since the comple of the Periyar Works, this bridge has always been in a more or dangerous condition, and for ten days or more at the end of Nov ber cart traffic across it was impossible. Many and frequent been our complaints to the Local Fund Board, Madura, but litt no notice is taken of them. I accordingly wrote to the Chief Secret Madras Government, pointing out the loss incurred by planter this district owing to the stoppage of traffic up this ghât, and gested that either a new ghât road, keeping on the right bank o Periyar overflow, be made, or that a suspension bridge be b instead of the present structure.

My suggestions have been forwarded to the Madura Local F Board for report, and the bridge has now been temporarily repa

TERMS MODERATE.

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

but I recommend members not to depend solely on the Cumbum Valley for rice supply, and the bridge may again collapse, without warning.

Periyar Bridge—Ferry.—The resolution passed at the last meeting was duly forwarded to the Dewan, and the Chief Engineer has been called upon for an estimate. I have heard, however, unofficially that an estimate has been sanctioned, but how soon the work will be put in hand is not known.

European District Magistrate.—The appointment of a 1st Class Magistrate to these Hills is under contemplation, but H.H.'s Government do not see their way to appoint Mr. Vernade or any other European to the post.

Crime in the Cumbum-Periacolum Valley.—All correspondence in connection with the Arnakal dacoity case was sent to the Planting Member of Council, but he does not recommend our going up to Government on the subject, as he considers the case not only weak but incomplete.

Its weakness is mainly owing to the Kangany's ignorance as to how to proceed against his assailants, and its incompleteness is due to Mr. Acworth having in the bustle of his departure for England either lost or mislaid one or more letters from the Police, as well as having not made a *précis* note in the Association letter book of some of his own.

The Superintendent of Police, Madura, has promised to institute a fresh enquiry into the case, and until after the hearing on the 10th instant of the case, taken by the Kangany against the police, dacoits, and others in the 2nd Class Magistrate's Court, at Uttamapalyam, I do not propose taking any further action.

U. P. A. S. I.—Your Committee have fixed this Association's subscription for the current year at one anna per acre on all cultivation over two years old, and half anna per acre on all cultivation under two years old. This will amount to about 350 rupees, part of which has already been paid.

A circular letter from the Chairman, to all producing Associations and Chambers of Commerce both in India and Ceylon, *in re* the re-opening of the mints, was circulated to the members of your Committee and met with their approval.

Medical Fund.—This Fund has now seen the first year of its existence, and I think we may congratulate ourselves on its establishment. To the efficient medical aid we have now provided for our coolies we may attribute the great decrease in sickness during the past year as well as to the more healthy season.

As you are aware the Association applied to H. H.'s Government for four medical grants-in-aid in support of the Fund: two only, however, were recommended by the Durbar Physician, which your Committee accepted. The Honorary Secretary wrote to the Dewan on the 20th September to this effect, but no reply has yet been received, neither have the grants been paid, although reminders have been sent on the 5th and 21st November, and again on 20th December. Your Chairman, however, took the opportunity of the British Resident passing through the district a few weeks ago to invoke his aid and support, and as Mr. Rees is shortly returning to Trevandrum, I trust the time will not be long before we obtain them.

Telegraph Subsidy.—Our share for the year ending March 31st, 1897, amounted to Rs. 181-5-3.

Accounts.—The accounts both of the Association and Medical Fund are laid on the table, and will be printed in the Proceedings. The former shows a small credit balance of As. 14-7. You will note that Mr. Acworth charged nothing for postages or attending the U. P. A. meeting as delegate. An acreage assessment of As. 4 per acre (exclusive of the Medical and American Tea Funds) will be required to meet this year's expenditure. The latter account shows a debit balance of Rs. 2,636-3-11, all of which but Rs. 236-3-11 will be met by the Government grant if paid from January 1st 1897.

I now place my resignation in your hands."

A. E. VEALE,
Honorary Secretary.

Proposed by Mr. Parker, and seconded by Mr. Laurie that the Report be formally adopted, and that a vote of thanks be accorded to the retiring Hon. Secretary for the energetic and successful manner in which he had carried on the duties of his office.—*Carried.*

The officers having resigned their posts, the Association proceeded to the election of those for the current year, when the ballot showed the following results :—

F. M. Parker, *Chairman.*
H. W. Baker, *Hon. Secretary.*
B. Laurie, R. S. Imray, R. A. Goldie, } *Committee.*
A. E. Veale, *Hon. Secretary, Medical Fund.*

The Chairman having briefly returned thanks, it was proposed by Mr. Imray, and seconded by the Hon. V. B. Wilbraham, that the Hon. Secretary of the Medical Fund be considered to be a member of the Committee.—*Carried.*

Read correspondence regarding the Arnakal dacoity case.—*Recorded.*

Medical Fund.—The meeting having gone into Committee on this subject, after a long discussion it was finally decided that the following postings should be ordered: the Doctor to reside at Pambanar and the four Apothecaries to be stationed at Bon Ami, Church Hill, Washpudingy and Arnakal, these positions being considered most central for the medical work of each Apothecary's division, and that the Committee do draw up and sanction any required plans, estimates or agreements with Messrs. Imray, Cole, Goldie and Holder respectively, as to the erection of the necessary buildings, their cost &c, on a basis of an annual 10 per cent. rental. Any changes involved in the above transfers to be carried out on completion of the required accommodation. The grouping of estates under each Apothecary having been approved, the details of same are appended hereto.

Proposed by Mr. Veale and seconded by Mr. Laurie, that the Hon. H. P. Hodgson be requested to again undertake the duties of Planting Member of Council, on the expiry of his present term of office.—*Carried.*

The accounts for the past year were then passed and the following papers were laid on the table :—

Proceedings of the Nilgiri Planters' Association.
" " Lower Pulneys Planters' Association.
" " Wynaad " "
" " Coorg " "
" " Shervaroy " " (2)

A vote of thanks to the Chairman and late Honorary Secretary who conducted the business, concluded the meeting.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 28th January, 1898.

S. E. Wynaad. DEVALA, 19*th January.*—*Weather.*—Since my last report the weather is bright, but at nights very cold, and on the 12th, 13th, 14th, and 15th there was very strong wind. *Crop.*—Paddy harvest is nearly being finished. *Grain.*—Salt 8, rice 8, cholum 19, and ragi 18 seers per rupee. *Health.*—Fever. *Labor.*—Sufficient.

Coorg. POLLI BETTA, 19*th January.*—*Weather.*—Overcast and rather threatening-looking on 14th, partially so on 15th. No rain, it is gratifying to note, resulted. *Crop.*—Picking and stripping still in progress. Pruning being pushed on with. Some blossom has been pushed out, but nothing to speak about. It will make no difference anyway. Price of grain has been going down very low in past two shandies. Fevers, coughs and colds prevalent still. *Interesting item.*—Planters' At Home to Chief Commissioner at Club yesterday evening.

Kil Kotagiri. NILGIRIS, 18*th January.*—Rain wanted for the young clearings; otherwise coffee doing well. Spike forward; promise very good for early blossoms. Artificials coming more and more into use; cattle manure is nearly abandoned. The estates belonging to the "Nilgiri Plantations Company" look lovely, and should do well next season. Pruning is started in a half-hearted way. Grain still high, but labour is still plentiful. The prices of crops have differed considerably this year on the different estates; one lot of the Nilgiris Plantations Company fetched an average of 95/- odd, while another estate fetched only 73/-. There are estates for sale, but the sellers want too much, and the buyers won't go up.

NOTES.

Caffeine and tea-house waste. In Cachar a large business is now done in buying up tea-house refuse of all sorts, especially sweepings which contain a large quantity of tea-dust. This they buy purely for the purpose of extracting the caffeine therefrom.

The American tea law and Canada.

An interesting effect of the American tea regulations is seen in the export of the rejected tea to Canada, where it is sold under all sorts of fancy names. The adulterated and faked teas being only Japanese and Chinese stuff, a further impetus will thus be given to the consumption of British-grown teas in the dominion.

Ceylon exports for 1897.

The decrease compared with 1896 in the export of coffee was 3,364 cwt., which brings down the total exports to 19,383 cwt. Cinchona shows a decrease of about 50 per cent., being only about ½ million pounds last year. Tea of course shows an increase, put at almost 8 million pounds, instead of 9 millions in Gow, Wilson's estimate. Cacao also shows an increase, the export last year being as much as 34½ thousand cwts. Cardamoms, cinnamon and dessicated cocoanuts also show a gratifying increase.

South Indian teas.

In their monthly report, dated London, 10th December 1897, which has only just reached us, Messrs. Arbuthnot & Co. (P. Macfadyen & Co.) say :—

"Nearly 3,500 pkgs. were brought forward, the average realized being 6¾ per lb. *versus* 7 per lb. for 3,000 pkgs. In October, a few of the Travancores had useful coloury liquor and were in good request, among the best being those from Vembenard, Glen Mary, Bon Ami, Fairfield, Penshurst, and Carady Goody, but the others were somewhat disappointing in cup. From the Neilgherries shipments from Kodanaad and New Hope were of fair flavor, and the one from Glendale was well competed for (being of fine quality)."

Tea-growing in Russia.

A very interesting letter on this subject has been published in the *Times of Ceylon*, written by a Ceylon planter who visited the famed estates personally. The deductions he draws from what he saw are as encouraging as any British planter could desire. What the actual cost is per lb. he could not ascertain, but as labour is 1*s.* 6*d.* per day, and no machinery is used, it must be very great. The duty, 1*s.* 10*d.* per lb., is certainly a great pull in favour of the Russian grower, but if the Russian planting industry expands to any degree, Government is very unlikely to let the indigenous tea go free. We hope to publish fuller details of the letter under notice in our next issue.

Prices of some "new products."

It may interest some of our more go-ahead readers to note the prices of certain so-called "new products," products, that is to say, to which planting attention is only fitfully attracted. In the *Chemist and Druggist* of the 1st instant, we note that crude *camphor* varies in price from 86*s.* to 91*s.* per cwt. *c. i. f.*; *ipecacuanha* 7*s.* 3*d.* to 7*s.* 6*d.* per oz. fine Rio; *oil of lemon-grass* up to 8*d.* per oz. at the highest; *orange-peel* from Malta and Tripoli 1*s.* per lb. good new quality. Old peel is worth 5*d.* to 6*d.* per lb.

Most, if not all, of the above products could be raised at a good profit and, moreover, without interfering in any serious manner with estate work.

Books, diaries, calendars, &c.

Mr. G. Parameswaram Pillai, B.A., the Editor of the *Madras Standard*, has sent us a copy of his book, "London and Paris through Indian Spectacles," whi has been running through his paper. Mr. Parameswara Pillai is certainly as keen an observer, if not keener, Europe as the ordinary globe-trotter is of India. T chief interest of the book will be of course to the educat native who has not yet had the pleasure of a Western tr Messrs. Davidson, of "Sirocco" fame, have sent us a ve handsome diary and blotter, replete of information co cerning their well-known inventions and containing also large store of useful facts for ready reference. We ha also to acknowledge a useful wall-calendar from Mess Addison & Co., of Madras.

Nyassaland a second Brazil?

One of our home exchanges h evidently got hold of some very cu ous ideas of the coffee industry British Central Africa. Its present yield is some 400 to or so, but, says the *H. & C. Mail*, "the time seems not distant when the Protectorate will become a dangero rival to Brazil in the European market." This is laying the colours just a little too thick! All the same, Nyass land coffee may in the near future, if the output increas at the same rate as it has been doing in the last few yea be a very serious competitor with East India. For t coffee grown there commands excellent prices in Londo while communications to the coast are improving. It news to us, though, that B. C. A. grows tea also.

Death to poochies.

The idea of using a light to attra night-flying insects is of course new thing, but the following of a successful Continen poochies-trap may be of value. By the way, how many our plantation pests develop into night-flying insect How about the unknown tea "flush-worm"?—

"A lamp is enclosed in a six-sided lantern, each of whose sides h an opening provided with a strong glass lens and a conical reflect through which insects seeking the light can enter. The upper p of the lantern consists of a pyramidal cover, furnished with ven lators that permit the passage of hot air, but prevent the escape insects. Below, it is closed by a similar pyramidal part invert which leads to a vessel with lids in which a sweet perfumed mixt has been placed. Having entered the lantern, the insects can get out, and they fall into the receptacle below from which they removed. The apparatus is placed in an open field or in a tree."

Liberian coffee in the Straits.

Things are not promising now days for growers of Liberian coff in the Straits at all events. T huge Brazil crops have so reduced the price of Liberi that the margin of profit is growing very narrow indeed. Straits planter, in fact, writes to an exchange, asserting th estates which cannot give 3½ piculs per acre (over 4 cwt without manuring will not be able to pay their way. F prices are assuredly very low. One correspondent affir that at Selangor the local price for No. 1 Liberian is abo 21 dollars per picul (133 lbs.) Once the price was dollars. The great fault lies apparently in the want of central curing establishment, and consequent bad curin bad grading, and poor packing. In fact, it is asserted th were the coffee sent home in barrels or tea-boxes, ve much higher prices would be obtained. The state of Stra coffee in London is said to be appalling,—dull, mould looking, and half-decayed. A large area of coffee la planted up in small blocks by Javanese in the old days high prices are now reverting to jungle, forming hotbe

of disease and weeds to the neighbouring plantations. Things don't look happy in the Malay peninsula.

The Zanzibar clove-crop. Advices from Zanzibar state, according to a home exchange, that all plantation-owners in Pemba report a very poor crop of cloves this year. Pemba will probably never again equal the big crops of former years. Many of the trees are getting old and woody, and only have a little foliage at the top, although, if they had been properly pruned, they might now have been in their prime. As it is, some of the shambas present the aspect of forests rather than plantations, and the trees are being used for timber. A very fine sample of Penang cloves recently received from London has been the subject of much interest both in Zanzibar and Pemba. This sample was specially selected to show what good cloves should be like when properly prepared for market. Several experiments have since been made with the object of ascertaining whether it is possible to obtain such good results in Zanzibar. Apparently, it is not enough to bestow attention upon the drying only. It is necessary that the buds, when they ripen, should be picked singly, not in bunches, as is usual in Zanzibar.

Grevellia gum. In view of the remunerative trade in gum, it is a great pity that planters have not been able to take their attention off the depressed state of crops and prices to that of attempting to turn to remunerative account the products of some of their shade and fuel trees. To most planters the very term "remunerative shade-trees" is an abomination. Yet, in the grevellia, we have a tree that might very possibly turn out to be a source of serious income. Briefly stated, the question resolves itself into this: two sorts of gum can be obtained from the tree. One sort exudes from the superficial layers of the bark in great quantities. This gives a milky white gum of no market value, though possessing great sticking powers. The other sort is obtained in some way or other from the inner layers of bark. It gives a clear, transparent gum of great value. What no one seems to know at present is how to extract the valuable gum by tapping or other means. The U. P. A. might well address the Reporter on Economic Products to the Government of India on the subject. If interest is excited on the subject, we shall be glad to re-publish all the information that has already appeared in these columns.

Quinine in 1897. In the quinine market, 1897 will be known as the year when "the turn" came that has been so long looked for, says the *Chemist and Druggist*. At the Amsterdam sales in January of this year, the lowest unit on record (2·12c. per half-kilo.) was reached. At that time bulk quinine was worth 9*d.* per oz. From January onwards the bark-unit began to improve, but quinine continued to decline for some months. In September, however, after a unit of 6·27c. had been reached at Amsterdam, the tide turned with a vengeance, and quinine rose from 9½*d.* to 12¾*d.* per oz. Since then the unit has reached 7·90c. (in November), and quinine has advanced to 1*s.* 3*d.* per oz. in second-hand. But so heavy were the quantities of bark thrown upon the market at Amsterdam that at the December auctions the unit dropped to 7·00c., and at the present time quinine can again be bought in Mincing Lane at 12½*d.* per oz. To form an idea of the quantities of quinine that are passed through the manufacturer's hands, it will suffice to state that the bark offered at this month's sales in Amsterdam represented 1,462,011 oz. of sulphate of quinine. The future of the article appears to be fairly hopeful. The cinchona-shipments from Java for the eleven months ending November 30 were 3,890,000 kilos., against 4,594,500, 4,098,650, 4,193,350 and 3,475,500 kilos. in the same periods of 1896, 1895, 1894, and 1893 respectively.

The tea trade in 1897. We commend the attention of our readers to Messrs. Gow, Wilson and Stanton's trade report for 1897, published in full in our Market Report with the exception of the elaborate table of figures. The yearly consumption of tea is about 500 million pounds, of which India and Ceylon now supply over half. The increase in consumption being more than that in production, the apprehension of over-supply is decidedly less alarming. The rate of consumption per head in England last year was the highest on record, being 5·83 lbs. against 5·67 in 1895. Compared with 1896 the consumption of Indian, Ceylon and China last year were: Indian 125½ M. against almost 123 M.; Ceylon 85½ M. against over 80¼ M.; China 17 M. against over 19¾ M. (a great falling off); other kinds (Java, Japan, etc.) 4 M. against nearly 4¾ M. With regard to foreign markets, trade follows the English language, for North America and Australia are our two most important external markets, though even taken all round, the expansion in new markets is most gratifying. The exchange of course was unduly high last year, being 1/3 15/32 against 1/2 13/32 in 1896. The average season price was also lower, *i.e.*, 8·99*d.* against 9·13*d.* for 1896. The average of the *calendar* year was 9*d.* last year against 8¾ in 1896. The total Indian production will be only about 2 million pounds more than the preceding season.

Turning to Ceylon, the increase in protection is expected to be about 9 million pounds. The 1897 price was 7·71*d.* against 8·21*d.* in 1896.

Java teas are improving greatly and are freely used in the United Kingdom.

"Odd-lots" of coffee in London. Year by year the increased business that has to be got through in the auction sales of coffee and tea exercises a pressure in the trade to frame regulations whereby such business can be profitably expedited. Tea brokers have long ago come to the conclusion that the sales of large and small breaks of tea should not be sandwiched together, and rules have been made that breaks under a certain size should be dealt with separately after the larger parts had all been disposed of. Last month a largely attended meeting of the coffee trade took place to consider the advisability of similar regulations with regard to the sale of the berry. Luckily for Indian planters the great majority of the members of the trade present declared against any alterations in the sale rules. The main objection to relegating small consignments together, and classing them as "odd-lots" to be sold after the large lots had been disposed of, was that the finest sorts of coffee imported into the country, *i.e.*, East India, Jamaica and Nyassaland coffee, would be relegated among these "odd-lots." On the other hand, it

was pointed out that during the last few years, and especially since the development of trade with Columbia, an enormous lot of small lots were placed on the market. The sale of these small lots took up far more time than that of large consignments, and it was alleged did not attract the desired competition of bidders. It was suggested, as an alternative proposal, that all East Indian and Ceylon be excluded from the present odd-lots rule, with the exception of triage, black, brown and cherry pickings. If this had been carried, it would have been possible of course to effect the change desired. It was, however, negatived by a substantial majority.

Tea shares in 1897.

Writing on the course of the market for tea shares in 1897, the *H. & C. Mail*, says:—"The marked feature of the earlier half of the year just drawing to a close was the continued steady appreciation in public favour among investors of the better known and soundest Indian and Ceylon Tea Companies shares. This continued to prevail almost up to the time of publication of the last of the 1896 reports. Further progress, however, in this direction was, at that juncture, stopped, first by Jubilee celebrations (which had an adverse influence on *all* stock business), but chiefly by the directly unfavourable effects of famine and plague, and subsequently of seismic disturbances (earthquakes), which specially affected Assam and the surrounding tea regions. These causes undoubtedly shook the confidence of investors in tea securities for a time, and caused a gradual but steady decline in share values (even those of the *preference* shares), which climaxed about November in the case of all excepting a few of the very highest class stocks. Even now, as the year closes, there has been no very marked recovery. The oldest and most favoured shares, it is true, still stand higher in most cases than they did a year ago, but most of the junior issues and the companies standing in the second rank are considerably lower than they then were. The prominent exceptions are the Assam Company, the Dooars Company, Doom Dooma, the Bramapootra Company, and the newly-formed Empire of India and Ceylon Company.

"The Rupee Exchange, owing to the persistence by the Indian Government in their closed-mint policy, has been kept up considerably higher than in 1896, and it now almost seems as if, for the present at least, a 1*s.* 3*d.* to 1*s.* 4*d.* rupee were likely to continue. This has, of course, been against planting profits, though the tendency of sterling prices for tea seems to be to assimilate itself to the new conditions. It may here be noted that the balance of Indian mercantile and banking opinion seems opposed to a continuance of the new policy, as tending to hamper the *export* trade, on which India and Ceylon mainly depend for their prosperity. A *stable* rupee, however, seems to exercise an extraordinary fascination upon the minds of a strong minority. So far as tea planting is concerned, it would appear that, *in the long run*, a stable rupee at not over 1*s.* 3*d.* to 1*s.* 4*d.* would not permanently injure the enterprise, as increased extension and concurrent over-production would probably thereby be curtailed."

Correspondence and matter for publication to be sent to Editor, this paper, Coonoor.

LETTERS TO THE EDITOR.

TO REAR DUCKS.

SIR,—In answer to the letter from "Duckling" in yo paper of the 8th January, I can say I have been rather succes ful with my ducklings. They must have lots of room to ru about and lots of clean water to play in. When first hatche out, ducklings should be fed on well-boiled rice mixed with little milk and water, and as they grow bigger, plain boiled ri with water, and later on bran and rice should be given. F the first month, young ducklings should be fed with the ric milk and water at least four times a day and a little at a time for the next few months three times a day will be enoug "Duckling" makes a mistake in giving ragi and the "noo choo" of rice to very young ducklings. I hope "Duckling will have more success in the future.

BIG DUCK.

GERMINATION OF SEED: A QUERY.

SIR,—I believe it to be generally held that to hasten an induce germination, it is often found that soaking in hot wat (as hot as the hand can bear it) previous to sowing is to be r commended. Being under the impression that the seed *Erythrina lithosperma* must be treated with all care to arrive a large percentage of germination, I soaked them as aforesai When the water was cool, I laid them out in a very thin lay on a nursery bed, between two layers of cloth covering th whole with a thick layer of fern. This I did because thought germination would be more successful thus, than sown direct in the bed. The weather succeeding this operatio was dry, and the seeds were kept carefully moistened. On th third day, I found to my great disgust that mildew had set i and so I immediately planted out the seed in the beds.

I have not the least idea how they will come up. Evident soaking such seed in hot water is a mistake.

SEED.

A VISIT TO THE E. LITHOSPERMA GARDENS.

SIR,—The very interesting accounts of the good effec of *E. L.*, when planted as shade amongst coffee that hav appeared, from time to time, in the columns of your pape cannot fail to have attracted the attention of all those inte ested in coffee, and as I have lately had the opportunity visiting both Mr. Ewart's and Mr. Nelson's estates, and see its wonderful recuperating effects, it has struck me that a fe lines on the subject may not be without interest to my brothe Coffee Planters. Mr. Nelson has gone so thoroughly into th *chemical* and *analytical* part of the business that it is quit unnecessary for me to do more than to allude to the wonderf chemical properties of the tree, and the resulting improvemen to the soil as shown in the analysis he has obtained. O

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain p ton:—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed fro the parent trees of above analysis at Rs.6 per pound contain about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere sa from the

MANAGER, ARIENKOW ESTATE,

Shencottah.

visiting the estates, which, I believe, had been more or less neglected before they passed into the hands of the present proprietors, I was first taken to a small field, in which no *E. L.* had been planted, but which had been manured steadily with *cattle manure*, fish, etc., and was fairly well shaded with trees of sorts. My own opinion, from the appearance of the coffee, was that the sooner it was abandoned the better for the proprietor! The next field, of the same age, similar soil, etc., *but shaded with E. L.*, showed a fine healthy growth of wood, and promised to give in the coming season a crop of at least 8 cwts. per acre. One field of younger coffee, about six to seven year's old, was a perfect sight, and reminded one of the good old days before leaf-disease had developed into the curse it has proved itself. And so on through both the properties, wherever *E. L.* has been planted, the coffee is in good heart, and although the trees still suffer from attacks of leaf-disease, they come round again in a most wonderful manner, which can only be attributed to the marvellous recuperative powers of what, I think, will prove to be the "Saviour of Coffee."

If these few hurried lines should be the means of inducing others to go in for *Erythrina lithosperma*, I am confident of the results that will be obtained, and can only regret that the existence of such a wonderful "natural fertilizer" has been so long unknown. I may perhaps be excused for mentioning, as some small "guarantee of good faith," that I have had a long experience in coffee, having opened my first tote in

"Sixty-two."

GENERAL ARTICLES.

THEORIES BY A NEW HAND.

Nurseries.

I have just been making some nurseries, for the reception of some few thousand *Erythrina lithosperma* seed by the way, and would like the advice of your more experienced writers on the subject, for the result, to my mind, is highly unsatisfactory. The only available ground I had was steep, having a fall of about 1 in 3. The beds being four feet broad, necessitated a lot of cutting, and the steepness of the banks resulted in a great deal of waste of land, say a couple of feet per bed almost. I obviated the loss of ground by supporting the lower sides of the beds by means of logs of wood, held up by two-foot pegs driven into soil. Well, the result is that the inside half of the bed consists largely of raw subsoil, while the outer half is good surface soil. In some places a thin layer of subsoil is over the whole surface of the bed. It scarcely needs pointing out what a wretched seed bed this gives to the plants.

Naturally, the result disgusted me not a little, though I hope the hardy *E. lithospermas* will come on all right, despite everything. Query, how could I have cut the beds so as to have an even depth of surface soil the whole area of the bed?

Not seeing any escape from the dilemma if cut beds are made, I straightway evolved a theory which I intend to carry out in practice at the next opportunity.

With flat land, of course, my theory has nothing to do. It is only with steep land of any gradient of 1 in 4 or more. After felling and clearing, the burn should be made as thorough as possible, then a deep digging with quintanies and mamotie-forks to, say, a foot or a foot and a half. Great care to be taken that the raw subsoil is not brought to the surface. The soil merely requires to be *loosened*, not turned over at all beyond the surface-soil depth. This, to my mind, is most important. I have during the last two years witnessed the very striking bad effects of subsoil being brought to the surface in nurseries. All large roots, stones, &c., removed, inspect the lay of the land carefully. Choose the depressions running down the face of the slope as your down paths, which might also serve as down-drains. For down-drains are absolutely necessary in my scheme.

Then take a road-tracer and peg out your beds at a careful slope of 1 in 40, or more if the land be very steep, from down-drain to down-drain. A convenient width for a bed is of course 4 feet, to allow of weeding, &c., easily from each side. But if the land is very steep, it will be better to make the beds narrower, say 3 feet. Allow 1½ feet for the path. The earth taken from the path (which will act as a cross drain, receiving the water from the three or four feet of bed surface above it) is placed of course on the bed below. The tracing and making of beds will begin of course at the top. The surface of the bed will be at a certain slope, it is true, but there can be no wash over such a small surface. If, owing to the steepness of the land, you have traced your beds at a greater slope than 1 in 40, it may be necessary to make an arresting bank of earth some 3 to 4 inches high across the bed. This is to arrest and turn off any water that may be flowing along instead of across the bed.

It looks extremely complicated on paper, but if you take the trouble to follow it out on a piece of paper, it will be seen how very simple it is in reality.

Now consider its advantages. There is a great saving in labour effected in not doing any cutting, while the danger of bringing up the raw subsoil to the surface and thus spoiling the seed-bed is entirely avoided. The disadvantages, what are they? The only suggestion of danger lies in wash. As it is usual to erect pandals of sorts over nurseries, the wash cannot be worth considering at all; for remember each bed is protected from the wash of the upper beds by its path which acts as a drain, so that the only wash each can suffer from is the wash from its own few feet (3 to 4 feet) of surface.

While I am on this subject, I should like to say a few words about the style of nursery I have often seen. To save the trouble of either carrying water a few feet up the hill, or of cutting a water-channel a few hundred feet, nurseries are often made as near the stream bed level as possible. The soil is never thoroughly drained. Ten to one, the subsoil is impervious clay. To "sweeten" the soil before planting out the seed, the land is often dug up carefully a couple of feet or so. The sour subsoil—for subsoil it may be, despite its rich loamy appearance—is brought up to the surface, and the seed-bed is spoilt for the next year. No wonder it is in such cases that complaints are made of the wretched way the young plants come up, and that lavish manuring is needed to bring them on in good time. At high elevations, to the disadvantages already enumerated, must be added the chilliness of the air in localities so near water, and the danger to the young plants from frost.

My pen has run away with me, and no mistake. I began by asking for advice, and end by ladling it out wholesale! Still, I should be glad of criticism of any sort.

PLANTING DIALOGUES.

I.

"WHAT'S the earthly use of knowing anything about science, all theory and bosh, when one has to earn one's living as a planter? It's my private belief, young fellow, you're doing more than merely wasting your time in reading those precious primers of yours. You're spoiling what little good was ever in you, if you want to become a 'practical planter.'" Thus spake old Jack Bentley, one of the finest specimens of the old-style planter I had come across. His chief listener was one of his assistants, young Green, who had ventured an attempt to teach his boss the elements of scientific agriculture. I was there too, of course, but merely sat tight and listened, jotting down the score. Green had often heard the same sort of advice from his boss, whenever he ventured to disclose a portion of the vast amount of scientific knowledge which he thought he possessed. He had paid his premium, not altogether the rule in South India, had worked out two years on the tote, and was sticking on till he got a paid billet.

"But look here, Bentley, you've told me that before. Do you really mean to say that agricultural science is of no use at all to the agriculturist out here, be he paddy farmer or coffee farmer? The principles of science are the same east and west, north and south. They apply equally well to planters out here as to farmers at home. It's ridiculous to"——

"Gently, my friend. I know you're A 1 at bucking. Bucking doesn't make the trees crop, dear Green. In your vast experience out here, has it ever struck you that the biggest talkers are usually the biggest failures? I don't want to be personal, you know. But if you're going back to first principles, we may as well change the subject. What I want to know is, how science can do us any good at all? How about leaf-disease?"——

"What good science can do us? Why, it can do us all the good in the world, as I demonstrated to you and the chaps at the Club last week."

"It didn't do you much good with the gloves, Green, my boy!" put in Jones, another of Bentley's assistants. This was a sore point with Green, for he fancied himself at boxing as at most things, and he found a very ugly, if unscientific, customer one night at the Club.

"Never mind about boxing, we're discussing the science of planting. You mentioned leaf-disease, Bentley. In Ceylon, as we all know, all that the then scientific knowledge could do was to predict the total extinction of coffee in the island. None of the practical planters of the day had any faith in the advice. The result is known to all."

"That's all right! So all that science could do with leaf-disease was to tell us that it couldn't do anything? Candid, at all events. All the good in the world, eh?"

And Bentley chuckled, as did we all. Decided score for Bentley. Slightly ruffled, Green stuck manfully to his guns.

"You must not forget that the disease was quite new to science, and that the climate of Ceylon was most favourable to the development of *Hemeleia vastatrix*. Travancore seems to be in much the same box. But elsewhere in South India leaf-disease, though bad enough, is not nearly so virulent. It is still bad enough to almost cripple the industry, and what are practical planters doing to mitiga its ravages?"

"All they can, my boy. If you can tell us anythin more, have it out."

"Yes, you are doing all you can, except, as Mother Seig says, 'the one thing.' What do practical planters kno about the disease at all? Some said shade kept it off. S everyone went in for shade. Then they found that shade ke off crops as well as disease. So the shade is being thinne out rapidly. Others pin their belief in what they ca autumn manuring, using the most various mixtures chemicals and artificials, without knowing anything abou them beyond their names, which are those of the men wh are reputed to have used them with success elsewhere."

"D——n your chemicals," cried Bentley. "Muck, m friend, muck, good old-fashioned muck, is all the plan want. Chemicals are stimulants, and neither man nor pla can live on stimulants!"

"No, but he can't live without them, can he?" put Green, smartly. For Bentley often swore that whisky, take in moderation—every man his own moderator—was indi pensable in the tropics. He lived up to his theory, too.

"Besides, how about damning chemicals when you can get enough of your beloved muck? How about those tons of mixture you ordered last month?"

"Well, well," growled Bentley, "I want to know what th 'one thing' is you bucked about now?"

"It is what I have been trying to demonstrate the who time. You have tried every possible thing you can think to cure leaf-disease. A couple of years or so ago you thoug you had got the best of the struggle. It's the old sto again now. You are ready, some of you, to try hair-braine patent schemes of curing the disease evolved by the fanc ful imaginations of retired planters, long out of touch wi latter-day planting conditions. Why, in the name of a that is sensible, cannot you club together to obtain the a of a scientist?"

"What good would that do? Haven't you just told that science has had a shoot at it already in Ceylon, an has been badly beaten? Stick to the point, young ma stick to the point."

"The climate and conditions of manuring, cultivation an so on were not the same in Ceylon as they are her Travancore is a nearer case in point. Why does not coff die out here as it did in those districts? It cannot altogether the climate, for, look at any of our good distric further north. A wet end of the country often gets alon just as well as the drier end. There must be somethin then beyond the climate. Some conditions of soil, shadin pruning, manuring or cultivation that tend to make th attacks severer. What are those conditions? How can practical, plodding planters possibly find time to tra them? Does it bore you too much to listen to me?"

An indistinct murmur which ended in a few impatie exclamations of "No, have it out as quickly as you can, an let's get on to tennis."

Green was too interested in hearing himself talk to chilled by the unflattering attitude of his listeners. H went on quicker than ever.

"Well, it's like this, you see. Supposing a scientist to a long tour round the district on the leaf-disease enquir He would visit as many representative estates as possibl note all details of climate, exposure, altitude, systems

manuring, and take careful samples of surface and sub-soils from the particular fields where leaf-disease was worst, and also from the healthiest fields. The samples analysed, he would probably find a very marked similarity in the leaf-disease soils, differing probably in some important characteristic from the healthy soils, which likewise would presumably bear a strong family resemblance to each other. Supposing the most important difference were to lie in the presence or absence of certain forms of iron compounds—to follow 'Nitric Acid's' argument—the next thing would be to find out how they were harmful. To a trained agricultural scientist this should not be difficult. To neutralise their harmful effects would be by no means impossible. There you are, my friends!"

"I'm hanged if I can see it! Your whole argument is based on 'supposing.' Supposing he couldn't find any difference at all in the soils, what then?"

"You would at all events have the satisfaction of knowing you had done your best," Green replied lamely.

"For my part, I much prefer the satisfaction of keeping my money in my pocket."

"If everyone held to that attitude, progress of any kind would be impossible. The man who first tried poonac for coffee had to suppose that it might succeed. Supposing no one had tried it, where would half the estates in the country be, as there certainly isn't enough cattle-manure to go round?"

"Besides, in estimating the chances of success of any particular experiment, one should be more or less guided by the results achieved in similar directions elsewhere. Typhoid, small-pox and many other diseases were once just as mysterious and fatal to men as leaf-disease now is to coffee. Science has practically conquered the former. Look at cholera in this country. Even if we haven't discovered the exact originating cause perhaps, we know enough to have stayed its ravages enormously. And as for——"

Here a chorus of yells put stop to all further spouting.

"Stow that, old man! We'll hear the rest of it next year. Send it to the 'P. O.' Editor; he'll appreciate it, you bet. We're off!"

With my help, Green actually acted on this last suggestion; and if this paper is printed, we may inflict further lots, 'cause Green hasn't got his billet yet. He says some one is sure to be attracted by the stuff and offer him a rattling good billet right off the reel—Poor Green!

ASSIMILABLE NITROGEN AND LEAF-DISEASE.

Retention of Soil, Nitric Acid.

Just as one may prove in a very exceptional way that soils of a highly ferrous nature, possess a peculiar difficulty in forming this product of oxidation, *i.e.*, Nitric Acid, so it is just as difficult for these soils to retain it. The most careless reasoning *must* show this to be so, and the lower the state of that oxidation of the soil, the poorer must its retentive power be. Yet that RETENTION, or retentive power of a soil for this important assimilable nitrogen, must admittedly be as vital a point as its FORMATION.

It is worthy of note that this peculiarly high ferrous nature, as revealed in Mr. Robinson's analyses, is common to all the coffee soils of South India at least (reasons already given for saying so). Consequently the ability of these soils to retain what little nitrates they can form is worthy of the closest notice. Especially so where tropical rainfalls have to be taken into consideration. For where, as before said, Nitric Acid in a soil is enabled to form and be kept, or at any rate given artificially and then kept and assimilated by the plant, then assuredly will follow the complete prevention of the disease if it has not gone too far (for at that time the roots are dried up and lose their power of feeding). A cure of the disease will even be effected. Health of soil, (*i.e.*, oxidation) and sufficiency of alkalies in the soil to catch, combine with and retain this acid (*i.e.*, Nitric Acid) must be essential for its success. Analyses of the diseased plant, together with analysis of the plant in health, will be produced to show the most striking lack of those glutinous or oleaginous bodies, composed of nitrogen and called Albumenoids or Proteids. These nitrogenous bodies of the plant, of much the same fluid consistency and composition as the white of egg, should be present to keep the coffee tree free of that typical dried-up hardened appearance, as they *certainly* are the strength and energy-givers without which the plant is simply a log, simply organic matter which gets decayed by bacteria. Lose these and the whole of strength and life must cease to exist in the tree. Their composition is something as follows: C_{53} H_y N_{16} S_1 O_{23}. Nitrogen forming a sixteenth part therefore of this glutinous compound. Analyses of the diseased plant will prove this loss of fluid bodies to you, and therefore I say that the retentive power of the soil for that assimilable nitrogen deserves the same attention which its formation should also receive, and in the coffee soils the *full* and *complete* analyses (they must be this) will prove how exceptionally poor both formation and retention are.

Poor oxidation means poor retention.

How does this poor retention show itself? Poor oxidation again and lack of alkalies. Take the first of these—oxidation, or rather lack of it. Let it be remembered this nitrogen food (Nitric Acid) is a gas, pure and simple. It is therefore perfectly soluble in water, occurs in the best of soils only as a small decimal point, but its extreme value remains nevertheless. With such extreme solubility in water, it allows itself (unlike the more solid mineral matters) to be freely carried away from the roots by each rainfall. Drainage waters from cultivated fields, and especially after the first rains, when the soil has formed it afresh, after the dry weather, are found impregnated with this food. The freedom or ease by which this proteid-forming constituent is removed from the soil by rainfall is too well known to need comment, but I wish to show that our South Indian soils have more difficulty in retaining this food than have other soils.

For instance, imagining a certain amount of Nitric Acid forms from organic matter (especially on the surface soils) it dissolves in water (*i.e.*, in rain water) taken from the roots, filters through a soil abounding in low oxides of iron—perhaps in the form of ferrous, perhaps as pyrites. Although these low oxides may not be actually soluble in water, yet, with the great greed iron has for oxygen, it is perfectly understandable how this water, charged with this product of oxidation, will pass through a soil and this N_2 O_5—this Nitric Acid, will yield up some of its oxygen (because it is an unstable compound) to these low oxides of iron. This, at the expense of that difficult forming Nitric Acid, would oxidise the iron, which has this greater avidity for oxygen. This assimilable nitrogen in cases of low oxide soils, simply acts as a carrier of oxygen to these low oxides of iron, and a source of loss, therefore, is found of that extremely important Nitric Acid. It has simply acted as a carrier of oxygen to the low oxides and itself becomes destroyed. There is a source of loss, therefore, *that must ensue* in soils of poor aeration, and one can well imagine how much greater that loss must be when it is carried to depths of three or four feet where that greater lack of oxygen exists. As a rule, three or four inches of rain would take this Nitric Acid below the roots only to return

again by capillary attraction to the surface in the next spell of fine weather; but in this case, taken to these much more unaerated depths, it must oxidise these low oxides and return again in poor quantity, to say the most. Here comes in a reason, therefore, I say, before applying Nitric Acid in the form of nitrate of soda or of nitrate of potash, of first oxidising the soil by means of drainage, tillage and certainly by the use of carbonate of lime. Part of the Carbonic Acid (CO_2) of the lime will, like the Nitric Acid, dissolve in water and carried by this means of rain through the soil, will part with some of its oxygen and convert these low oxides to the higher, *i.e.*, the ferrous state to the ferric. When Nitric Acid, therefore, meets these low iron oxides, it will not become dioxidised, it will not become merely a carrier of oxygen, but remain itself that useful food because tillage, drainage, and that strong oxidising agent, carbonate of lime, have done their work beforehand and prepared its way. Hence the good results in practice that are observable in combating Leaf-disease by the use of lime, previous to a nitrate application or an organic manure like oil-cake.

Ferric Nitrate. Ferric nitrate is an insoluble (in water) compound of Nitric Acid and iron. It was Knopp, I think, who noticed that nitrate of soda placed on an iron soil, showed its effects on vegetation much to his surprise for a whole year. He accounted for this by the Nitric Acid leaving its soda base and attaching itself to the much stronger base of iron in its highest oxidised state, and through every adversity of rainfall, kept that vegetation rich in its nitrogen principles a whole year. It was mentioned before that a 2-oz. application of soda nitrate showed this effect in giving a nitrogenous appearance and keeping off Leaf-disease a whole year. It was mentioned also the soil was almost nothing but stones both surface and sub-soil, while the organic matter of the soil contained a high percentage of sand. There was every reason, therefore, for safely pre-judging that the iron in this soil by perfect natural drainage, was exceptionally rich in iron in its highest state of oxidation. If, therefore, this was so, a strong base for Nitric Acid was afforded, and since ferric nitrate is *insoluble in water* but *soluble in weak acids*, it would be clear how Nitric Acid could be fixed in the soil by this means during the heaviest of tropical rainfalls, while at the same time this ferric nitrate (soluble in weak acids) would be attacked by the weak acids of and assimilated by the roots of the plant. Other bases or other nitrates, say of soda, lime, magnesia, lime being perfectly soluble in water would be carried away from the roots and lost by rainfall.

Leave alone however any such question, it is repeated that on that obviously healthy soil, this 2-oz. of nitrate of soda placed on in March entirely prevented disease for one year, carrying it through two monsoons and bearing a 5-cwt. crop, while that part of the estate previously treated with lime carried its effects for still a greater period. At any rate the low oxide state of soil, such as these coffee soils show themselves to be, must be fatal to Nitric Acid preservation, while it seems, by Knopp's suggestion that iron can, in its highest state of oxidation prove itself the best preserver of this assimilable nitrogen. The whole thing, however, needs laboratory experiments to prove what is the best way of aiding the soil to retain this fugitive of fugitive foods under heavy rainfall.

Sulphate of iron (Ferrous sulphate) through its great solubility (besides hindering the formation of Nitric Acid) must have still worse effects on Nitric Acid, than the lesser soluble ferrous silicates. As one knows, it forms in the less unaerated, wet and highly organic matter soils. Being perfectly soluble, it can travel freely through the soils, and if such a compound *does* occur in these soils (the acidity of some of these s rather point to it) it is easy to see how this low oxide in hot or dry weather can ascend through capillary attracti meet Nitric Acid in its ascent and destroy it, while it itsel converted to the ferric sulphate. Maercker has shown t where $1\frac{1}{4}$ % of this objectionable salt occurs, then there found no trace of Nitric Acid. Leave the whole question soluble ferrous alone however, it is possible it rarely occurs coffee soils, and that the acidity of the soils is due to hu acids, on the other hand *it may be* there and should be *very ca fully* tested for, and if found, corrected.

At any rate ferrous soils in every way are against the rete tion of Nitric Acid.

Lack of Alkalies in soil. Lack of alkalies in soil would be further aid in the loss of assimilal nitrogen. It will be noticed by t analyses of Mr. Robinson, that four out of six of the so analysed have acid traces, showing insufficiency of alkalies combine with and neutralize these acids, whatever that sou of acidity is *but proving lack of alkalies.*

Were these various uncombined (with acid) bases such lime, magnesia, potash, soda more plentiful, there would more resistance to Nitric Acid gas in water being lost. That rainfall, in charging itself with this Nitric Acid which h formed in the drier months, filtering through the soils, wou come in contact with one or some of these alkalies, whic though perhaps not stopping, would certainly give a distinct hindering action to this valuable acid. A nitrate of one those or other bases would form and certainly must tend to gi a check to this food which is ever ready to get lost by rainf in the most healthy of healthy soils.

Laboratory experiments might be useful. Again the whole thing needs caref laboratory experiments to prove wh will make the soils most retentive of th food. Just as in Mr. Robinson's analys the retaining power of a soil for water is tested for, so c this retaining power of a soil for Nitric Acid in both wet a dry weather be tested, for it would be most helpful to know t result, especially as nitrogen is such an expensive manure a especially as in every way it is possible to prove Leaf-disea can be entirely discounted by its presence if in an assimilal form.

For instance, a sample of soil could be taken and a solution nitrate of soda of known strength could be poured on to t soil. Allowing a certain lapse of time for chemical action take place, a known quantity of water, say equal to ten inch of rain, could be passed through the soil. Knowing the quant of Nitric Acid given to the soil by this nitrate of soda soluti a most useful test could be made to see how much Nitric Ac remains in the soil after this equivalent of ten inches of ra had been poured through it.

But more interesting still would it be to take a like sample soil, place it into a thoroughly good state of oxidation, by mea of lime or potash, place on the same an amount of nitrate soda as in former experiment, pass precisely the same amount water through it and at the same rate as before, and then te how much the retentive power for this Nitric Acid has be improved and increased.

This would certainly be a guide to know how this constitue which has to form these soluble albumenoids of the plant, cou be better retained by the soil, while the test would be a simple ou

Actual stubbornness of soils. Mr. Robinson's analyses of the coff soils have been brought forward, believi that they show a still higher state of l oxidation and lack of health than has hitherto been shown, y

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

efore treatment in the laboratory they had the most unfair reatment, a treatment which should have given, one would ink, a totally different appearance to the oxidation of these ils. Unsuspecting that these soils so lacked that life principle xygen, they were sent home in porous gunny bags. For three onths they laid about before analysis was made, air poured rough them to such an extent that all moisture had left them d they were eventually after these months of unnatural eration, poured out on to the analyist's table like a dry owder. Facts which one certainly would have thought would ntirely alter their nature—place them into a better state of xidation and health than they showed. With all this un-irness to them before treatment, they show these exceptional igh amounts of ferrous—these low amounts of carbonic acid, ese low amounts of soluble salts and that frequent acidity. t is nothing more than a direct stubbornness—analyses after ch a treatment, allow me to say so. The cause of it can only e low oxides of iron, perhaps pyrites, continually splitting up y oxidation and giving continual new work for oxygen to do. o see the soils having gone through such exceptionally good pportunities for oxidation as these did, it only makes the form-tion and low retentive powers of these soils for Nitric Acid, he more impressive. Only in one set of agricultural books do I now that this class of soils is treated upon at all at length and hat is in Storer.

NITRIC ACID.

THE SUNFLOWER.

PROBABLY the cultivation of no other plant has, during the last few ears, increased so greatly as that of the sunflower. In Russia alone early a million acres are annually devoted to its cultivation, while n Germany and other European States it is grown in immense uantities. Some of our farmers think that in the large, hand-ome, smiling face of the sunflower they can see that there is money o be made by its cultivation. That there is a good opening to row sufficient for home consumption seems to be beyond the range f doubt.

The oil is of great value, scarcely inferior to that obtained from he olive; it is of a clear pale yellow colour, limpid, almost odourless nd with a pleasant mild taste. For salads and many other omestic purposes it is equal to, if not superior to, olive oil. It nakes excellent soap, of great softness. Sunflower zweep (Sun-lour soap) is extensively used throughout Germany, Switzerland, nd Russia. For painting, especially for greens and blues, it is argely employed.

The seeds, roasted and ground, make a good substitute for coffee; hey also make demulcent and soothing emulsions. A fine sweet read is made from the flower. The flowers produce a large amount f honey; they also give a fine yellow dye. The tall woody stems, when burnt, produce a valuable potash. The pith of the stems may e used in surgery, instead of moxa. The leaves, either fresh or dry, nake excellent fodder. By treating the stems like flax, a very fine ibre is produced, nearly as fine as silk.

Poultry, pigeons, and small birds are very fond of the seeds. If a ead of the ripe seed is suspended near a window in the cold weather, t will prove a never-failing source of attraction to many of the small irds. Fowls must not be overfed with the seeds, or they will put n too much fat, and reduce egg production, but given in moderation, he seeds will, during the winter, answer as well as animal food, and ssist in producing early eggs.

When mixed with other food, horses and cattle take to the seeds eadily. One pint of seed given to a horse per night produces good ffects. Pigs fatten very quickly on the seed alone.

When the seed is used in the manufacturing of oil, the refuse nakes excellent oil cake for fattening cattle, and for this purpose is sed largely in Russia, Holland, Sweden, Denmark, and also in England, where it is regarded as the best obtainable food. It is aid to be superior to rape or hemp seed in its flesh-producing roperties, and one German farmer reports that he increased the lesh of an ox 2lb. a day by feeding him on sunflower cake. An ncreased milk supply is said to be produced when fed to cows.

The growth of the plant in favourable soils is very rapid, and its absorbing and exhaling power very large. It is, therefore, suitable for growing around unhealthy low localities. A good-sized plant is said by Lacoppidan to exhale 1½ lb. of water during a hot day.

The sunflower is very exhausting to soils. Although it will grow in many kinds of land, the best results are obtained from that of a deep rich calcareous nature. Old mortar makes an excellent manure for it. Open, porous land is infinitely better than a close, compacted soil. Sandy or stony soils require to be heavily manured. The impoverishment of the soil by its culture can be remedied greatly by burning the stalks and spreading the ashes over the surface, and the land could, of course, be kept in good heart by a liberal use of bone-dust, blood manure, guano, or other artificial fertilizer. In Russia, if the stalks and leaves are left in the land used as manure, no further fertilizer is needed for some half-dozen years.

In good land and in ordinary seasons the plants require no artificial watering, but irrigation is necessary sometimes.

There are several varieties of the sunflower. The white-seeded one is said to produce the most oil, but the large black-seeded kind, called the Russian, is the best for poultry and cattle-feeding. In Europe a dwarf species named *Helianthus Indicus* is reputed to be the most profitable for general cultivation.

All the commercial kinds of sunflowers are annuals, and attain maturity in about five months from the time of sowing the seed. Six pounds of seed will sow an acre. From September to early November is the best time for sowing; the exact time must be governed by the locality, whether an early or late one. The season must also be taken into account. Directly all fear of frost has vanished, then sow the seed. Three feet by three feet is a good distance for plants of the larger growing kind to stand, but the dwarfer varieties may be grown closer. The hoe or scarifier must be kept going between the plants to destroy weeds and keep the soil loose.

When the leaves of the plant are dry, the seeds are usually ripe, and the heads fit together. If the seeds are allowed to get too ripe, the wind will shake the seed out. Birds may do considerable damage, and in removing the heads a quantity of seed will drop.

The heads must not be placed in heaps, or they will soon rot; neither should they be put in a close building, but in a good airy shed, like that used for curing leaf tobacco. When a small quantity only is grown, the seeds may be readily taken out of the heads, or they may be thrashed out, and then screened through a fan-mill. If it is intended to keep the seeds for a time, whether in the husk or after being cleaned, it is imperative that they be thoroughly dry, or they will soon become mouldy and spoil.

An acre of plants well grown will produce up to fifty bushels of seed; each bushel will yield a gallon of oil, and 1,500 lb. of oil cake may be obtained from the acre. If the stalks are burnt, half a ton of potash will be produced.

Wheat succeeds splendidly after a crop of sunflower. It is stated that locusts will not touch the growing plant, and cattle do not care very much about it.

At present there is no great demand for sunflower seed, but if it could be produced pretty cheaply, so that it would compete with maize and other poultry foods, it would become largely in demand. Its value is becoming more and more known daily. Our farmers should commence the cultivation of the sunflower by first growing a little for home use.—*Queenslander.*

BRICK TEA.

PROCESSES OF MANUFACTURE.

WE are accustomed to hear so much about the increasing consumption of tea on the continent, and of inferior qualities being preferred to the good liquoring classes, especially about brick tea, which is in great demand in Russia, that it may serve a useful purpose if we give our readers some idea as to the process of manufacture of brick tea. There can be no doubt that the reason for the importation of brick tea into the Russian market in such large quantities is the facility of carriage, and the economy in freight charges. Indian consumers, however, are accustomed to drink tea of the finest colour and flavour, and know how to appreciate the article,

nothing but the best satisfying the palates of English and Anglo-Indian tea drinkers, whether at home or in India. Brick tea is made in Thibet and China, but it is very doubtful whether residents in this country have ever had the hardihood to try the product of either country. It may interest them, therefore, to learn how this compressed tea is manipulated.

The following is the process in Thibet :—

1*st.*—It must be understood, that brick tea is not made from the young leaves like ours, but from the old ones cut off in the pruning in the cold weather.

These leaves, stripped from the branches that have been pruned off, are *boiled* in a large cauldron in water passed through ashes, (keranee ka panee) until the water is nearly evaporated, and the leaves are in a glutinous state, which takes about an hour and a half.

2*nd.*—On being taken out of the cauldron they are beaten with a large wooden mallet, in a box made sufficiently strong for the purpose, until they are in a pulpy state.

3*rd.*—They are hammered into the mould with the mallet, and a little congee-water from boiled rice, or starch, is mixed with them to help them to cake. Of course the leaves should be slightly above the mould when it is full, as the pressure put upon it soon brings the brick down to its proper size.

4*th.*—They are put into the press, and kept there for 24 hours. Of course the press is managed in such a way that any number of bricks can be put in at the same time, and those that are ready can be taken out without interfering with the rest.

5*th.*—On taking the bricks out of the press, they should not be taken out of the moulds at once, but left for 12 hours or so; and on being taken out they should be placed in a rack over a slow fire that they may *thoroughly dry*:—this is very important, or they will get mouldy.

6*th.*—They should then be stacked in a dry place, such as the loft of a drying godown, and should be occasionally looked to and wiped, if any signs of mildew are observable on them.

This is the whole process of manufacture. The apparatus required is--a copper "dekchee." The largest procurable is the best. A stoutly made box and mallet. The moulds, 15 inches long by 9 inches broad, by 6 inches deep. These should be dove-tailed with a pin to go through the corners so that they can be opened out and put together again without injury to them or their contents.

The best kind of press to use in a beam about 20 feet long fixed at one end on an axle and weighted at the other end. Any amount of pressure can be put on by this means, and it is preferable to a screw, as it is a continual pressure.

The following is the method of producing brick tea in China :—

The first operation is to sift the dust and reject all the sand and rubbish contained in it, usually amounting to about 5 per cent. It is then placed in a winnowing machine having three different sized sieves, with troughs corresponding, and passed into baskets. The residue, which is too coarse to pass any of the sieves, is taken out and trodden until it is reduced to the proper consistency, when it is placed in iron pans over a charcoal fire until it is sufficiently brittle when it is again taken to be winnowed, and this operation is repeated until it has all been sifted to the requisite degree of fineness. Three sizes are produced, the coarser ones being employed to constitute the brick, while the finest dust is only used as a facing. The dust having been properly sifted, the next step is to prepare it for pressing, and this is done by exposing it to the action of steam for three minutes, and it is this steaming that robs brick tea of its scent and flavour, and for which a remedy is eagerly sought. The old-fashioned apparatus of native design consists of six iron boilers heated by charcoal, and having spaces over, which are fitted with rattan covers. When the dust is to be steamed, it is spread out on a sheet of cotton cloth placed over the boiler and covered up; but with the improved European apparatus the dust is simply put into iron boxes and the steam then passed through them. After having been sufficiently steamed to make it adhesive, the dust is put into a strong wooden mould, on the moveable cover of which the trade mark of the "hong" or firm is engraved, (so as to leave the corresponding impression on the brick) and firmly wedged down. It is then pressed and placed on one side for two or three hours to cool. Each brick should weigh one catty, and all those that do not come up to the proper standard of weight, or are defective in any way, are rejected and re-made. For this purpose they are taken t rotatory mill, constructed of two heavy circular stones, moved b horizontal wooden bar, and working in a channel where the c demned bricks are thrown, and crushed as the wheels pass over th Having again become dust, the operation already described is in its details, repeated. The hand press turns out sixty baskets a c with 25 per cent. failure bricks, while the steam press produ eighty baskets a day with only five per cent. of bad work, and saving by the employment of the improved machinery, amou to one tael a basket, or according to the above stated outturn, eig taels a day, or about £20 sterling. The bricks found to be cor in weight and free from defects are stored in the drying-room f week when they are carefully wrapped separately in paper, packed in bamboo baskets containing sixty-four bricks each. Gr brick tea is made in the same manner, but of leaf, not dust, the bricks are larger, weighing two pounds and a half each,thirty going to a basket when packed for export.

THE PLANTER.

DISTRICT ASSOCIATIONS.

WYNAAD.

PROCEEDINGS of an Extraordinary General Meeting held at Mep Club on December 22nd, 1897. *Present*:—MESSRS. ABBOTT ATZENWILER, BEHR, DAY, DE FONBLANQUE, R. LAMB, MACKIN D. MACKENZIE, W. R. MACKENZIE, B. MALCOLM, J. R. MALCOL S. MALCOLM, POWELL, ROBINSON, WADDINGTON, R. K. WAL WINTERBOTHAM, WEST, WRIGHT, and HOCKIN, *Honorary Secret* Mr. R. K. WALKER *in the chair*.

1. Proposed by Mr. Lamb, and seconded by Mr. de Fonblan that a Chairman and Committee be appointed for this Associa annually. Mr. Atzenwiler, seconded by Mr. Winterbotham, prop as an amendment that matters remain *in statu quo*. For the am ment 3; against 14. The amendment was lost.

For the original proposition 13; against 3. The proposition carried.

2. Proposed by Mr. Waddington, seconded by Mr. W Mackenzie, that the Committee be composed of 2 members for Vayitri, 2 for the Meppadi, 1 for the Vellera Mulla district, and Chairman and Honorary Secretary *ex-officio*. Carried *nem. con.*

3. Resolved: that the Committee be elected by ballot, and Chairman and Honorary Secretary by nomination and a sho hands at the Annual General Meeting.

4. Some discussion took place as to the number of Commi and general meetings to be held annually. It was generally ag that the general meetings should be held at not longer inter than once a quarter, and oftener if the Committee thoug necessary, so that the general body of members may not lose interest they now take in the affairs of the Association. Also Committee meetings should be held about once a month, unless emergent business should come up for disposal. Some mem expressed a wish that general meetings might always be held on first Wednesday in the month, and longer notice of the busines be discussed given than they had lately had.

No resolution, however, was passed on any of these subjects.

5. Read letter from the Chairman, U. P. A. S. I., announcing sudden death of Mr. Digby T. Brett, Chairman of the Plan Conference in 1893, and of the United Planters' Association in 1 The Honorary Secretary was requested to write to Mrs. D. T. B expressing the Association's regret and sympathy.

6. *Election of New Members.*—Mr. Glennie was elected a mem of the Association. A vote of thanks to the chair closed proceedings.

GOLD AND BLOOD.

MANY years ago I knew a man who expended a great part of a large fortune in buying gold, in coin and in bars. This he melted, and with human blood and other unique ingredients, laboured secretly to prepare a mixture that should arrest all disease, renew vitality, and prolong life indefinitely. I need hardly say that he failed. Not only did he fail, but one day an explosion took place in his laboratory which destroyed the fruits of his toil and left him senseless and badly wounded amid the wreck. The rest of his days were passed in an asylum.

Yet he was not the first man who tried that same experiment, nor by thousands. To find the elixir of life was one of the main purposes of the science of alchemy, the barbaric ancestor of the modern science of chemistry. But all that is now discredited. No doctor or student of healing even pretends to possess or to seek an essence of life.

What is undertaken, however, and successfully, is to ascertain the truth about Nature's functions, and to help her perform them when they are impeded by disease.

Illustration of what can be done on his line are plentiful. Here is one: "Twelve years ago," says Mrs. Eliza Matcham, of Armitage House, Sutton-on-Hull, "I had an attack of rheumatic fever. At the same time I had a bad taste in the mouth, poor appetite, and pain and weight at the chest after eating. I frequently spat up a quantity of greasy, fatty matter. Later I was afflicted with rheumatism in my hands and feet. Then I fell into a state of debility which continued year after year. I spent a great deal of money in doctoring, all to no purpose. Finally I was induced to try your medicine. In a short time my food agreed with me, the sickness ceased, I grew stronger, and the rheumatism by degrees abated. Now by taking your remedy occasionally I keep in good health. (Signed) Mrs. Eliza Matcham, June 2nd, 1893."

"For some time previous to 1887," writes another, "I was troubled with a digestive disorder. In the autumn of that year (1887) I got a severe cold, which brought on rheumatism and lumbago. I had great pain in the back and also in the joints. I consulted a doctor, who gave me medicines, and advised me to go to Buxton. I did so, but I am bound to say obtained little benefit from it.

"In January, 1888, I had another attack of rheumatic fever, which brought me down into a very low and feeble condition. For days and days together I was unable to eat or sleep. It was only by hardship and pain that I got about at all. Whilst on a visit to Little Downham, Cambridgeshire, some friends told me of the medicine furnished by you. I used it, and soon found relief, and gained strength. Cheered up and encouraged by this, I continued taking it, and now, by an occasional dose, I keep wholly free from rheumatism and other troubles. (Signed) Philip Hopkin, 20, Maude Street, Grimsby, November 14th, 1893."

The eccentric man alluded to in the first part of this article failed to cure any disease with his odd brew. It was costly, too, as I said. Blood is cheap enough, but bars of gold come high. He was a fanatic and a fool.

But here we have two instances in which rheumatism, a common and dangerous ailment, was cured by Mother Seigel's Curative Syrup, a remedy made not from blood and gold, but from the heating herbs of the fields and forests. And why was it cured thus so speedily and with such seeming ease? Because rheumatism is not a disease of itself, but a symptom of indigestion and dyspepsia. It is *this* universal plague that the Syrup scatters and drives away, its children following after. Thus we keep our blood in our veins and our gold—if we have any—in our pockets.

MARKET REPORT.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, dated December 31st, 1897, says :—

Home Consumption of Tea reached a higher figure in 1897 than ever before, viz. :—about lbs. 232,000,000 against lbs. 227,785,509 in 1896, and lbs. 221,800,137 in 1895. This increase consisted entirely of Teas from India and Ceylon; their use has steadily increased year by year, not only at home but also in important foreign and colonial markets.

The total consumption of British Grown Tea amounted to about lbs. 261,000,000 in 1897, against lbs. 245,559,775 in 1896, and lbs. 227,106,249 in 1895, viz. :—

	1897. Estimating December.	1896.	1895.	1894.
United Kingdom ...	211,000,000	203,235,573	190,367,123	188,535,730
Foreign and Colonial Markets ...	50,000,000	42,324,202	36,739,126	28,773,885
	261,000,000	245,559,775	227,106,249	217,309,616

As only about 500,000,000 lbs. of Tea are used in the civilized world, more than 50 per cent. was supplied by India and Ceylon in 1897. The increase in consumption was more than that in production. The apprehension of over-supply appears therefore to be decidedly less threatening.

Home Trade. Not only has consumption increased, but the rate per head of population rose above any previous year, viz.: lbs. 5·83, against lbs. 5·73 in 1896, and lbs. 5·67 in 1895.

Indian and Ceylon Teas have almost beaten China out of the market, the quantities of each of the former used being higher than ever, while China has again fallen away :

	Indian lbs.	Ceylon lbs.	China lbs.	Other Kinds lbs.
1897 ...	125,500,000	85,500,000	17,000,000	4,000,000
1896 ..	122,941,098	80,294,680	19,831,680	4,718,256

New Markets. The expansion in this branch of the trade, as shown above, is most encouraging, and justifies the hope that before long outside markets will be sufficient to absorb any probable increase in production. It is remarkable that wherever English is spoken, the trade in British grown Tea has gradually expanded, until now Australia and North America are our two most important external markets, while there is little doubt that South Africa will soon become a prominent consumer of British grown Tea. Russia also uses increasing quantities of Ceylon Tea.

Production. During the year just closed Tea production has been attended with somewhat serious difficulties, viz. :—

1. The exceptionally high rate of exchange ruling, viz.: 1/3$\frac{15}{32}$ against 1/2$\frac{13}{32}$ in 1896.

2. The lower average price realized by the crop compared with that of 1896.

3. Dearness of Rice (the Coolies' food) caused by the famine in India.

These causes affected India and Ceylon, but India suffered another calamity in the recent earthquake which caused direct damage to some estates, and indirectly affected many more.

Indian. The quality of the crop was fair. Assam was up to the high character of last season. Dooars and Cachar were good, Darjeeling was on the whole poor, and Sylhet indifferent.

The following table shows the average price obtained for Teas from the different districts since the commencement of the season, the average for all Teas from that date being 8·99*d.* against 9·13*d.* for corresponding period last season :—

	Pkgs.	Price.	Pkgs.	Price.
Assam	321,477	10¼	313,562	10
Cachar and Sylhet ...	173,723	7	162,773	7½
Chittagong	4,367	7¼	2,111	7½
Chota Nagpore	804	4¾	1,002	4¾
Darjeeling	48,361	11¼	45,138	1/0¼
Dooars	77,311	7¾	85,271	7½
Kangra, &c.	4,936	7½	3,938	7
Neilgherry	4,483	7	2,353	7
Terai	16,800	7¼	9,653	7
Travancore	19,844	6½	17,059	7

The total output will apparently be about lbs. 151,000,000 against about lbs. 149,000,000 last season.

The market has not been subject to violent fluctuations; the tendency throughout has been to lower rates, and perhaps at no period in the history of the trade were Teas of such good quality selling for equally low prices. The average price obtained for all Teas sold on garden account during 1897 was 9*d.* against 8¾*d.* in 1896.

Ceylon. A comparatively small increase took place in the crop; the quality about equalled that of recent years, being of very fair average. The outturn is expected to reach about lbs. 117,000,000 against lbs. 108,000,000 last year. The price obtained for Teas sold in London in 1897 was 7·71*d.* against 8·21*d.* in 1896.

Java. Teas of good quality are now produced by a few of the best gardens and are used freely in the United Kingdom, while the growth of other Estates continues in favor in various export markets.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 4th February, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Lower Pulneys.

18th January.—Weather.—From 11th to 14th January we had dull muggy weather, thick mist, with a driving rain, day and night; average rain during these four days: Lower Pulneys, 1 inch 10 cents; Siroo-mullay Hills, 1 inch 40 cents. These rains are unusual for this time of the year; they will bring forward some of the blossom, especially on the lower elevations, and a heavy flush of new wood. On 15th it was bright and clear again, and we hope it will remain so till March. *Crops.*—About half in. *Pruning and Forking*—Commenced on some estates. *Health.*—Good. *Labour.*—Sufficient.

Nellampatty (British).

26th January.—Weather.—Strong winds have been blowing all this month and show no signs of abating. Rain has fallen twice since my last report, but not in sufficient quantity to do any material damage. I had 30 cents on Saturday last, but it was not at all general. *Crops.*—Some places have still a little to gather, but majority have finished and pruning is in full swing. In a few cases more than estimate has been gathered, and all over out turns are rather better than usual. *Plant-diseases.*—Very little of any kind showing. *General Health.*—Fair; fever fairly prevalent among coolies. *Labour.*—One or two estates have paid off a lot of labour, and by the end of this month I think about half the coolies will have gone. *Interesting Items.*—It may be news to some people that on these Hills there are no jackals, no hares, and very very seldom do we ever see a crow. One hare was seen the other day, and this is, I think, the second in the memory of the oldest inhabitant.

SUPERPHOSPHATE OF LIME AND HOW IT BEHAVES.

THE great "chemical change" which some of our readers declare to be passing over the planting community seems to have hung fire to such a degree that it requires a very persistent stimulus to keep it going. The most that has taken place appears to be that a rush is being made for what are called chemicals and "artificials." To imagine that any advice is needed as to their proper and economical application seems, to many, perfectly ridiculous. For confirmation of this supposition, we would refer doubters to

the resolutions passed at their recent District Association Meetings.

A very large proportion of those men who are yearly losing confidence in their old stand-by, cattle manure, have only the slightest acquaintance with the foreign substitutes they are now eager for. Of agricultural chemistry they have heard, perhaps. Some talk in a confused way of nitrates and phosphates. Few have more than a superficial knowledge of the subject they at times discuss so glibly. Otherwise, we would never have had the planting industry of South India deliberately rejecting the proposal made at the last U. P. A. Meeting of securing the services of an agricultural expert.

Let us take the case of superphosphates of lime. Every planter has at least heard of its name. Some know why it should be used. A tiny minority know how to use it. What is then superphosphate of lime, why is it used at all, and how should it be used ?

A writer in a Colonial paper answers these questions very clearly. Superphosphate of lime is a soluble compound of phosphoric acid, lime and sulphuric acid. Phosphoric acid is one of the four important—because rarely found in sufficient abundance—elements of plant food. That phosphates play a most important part in plant economy is a commonplace now, but its discovery by Baron Liebig, the founder of agricultural chemistry, was romantic. He found that a certain very fertile wheat district in Sweden owed its remarkably good crops to the presence of a great quantity of decaying bones in the soil. For a great battle had been fought on the spot, and the fields were a huge graveyard. Analysing both the wheat and the bones, Liebig found a large proportion of phosphoric acid in each. The conclusion was inevitable, supported as it was by further tests and experiments, that phosphoric acid was much needed by wheat, and that bones could supply this want. But Liebig also found that raw bones took a very long time to give up all their phosphoric acid. He discovered a way to hasten the process. This was effected by adding sulphuric acid to the bones, which dissolved them into a soft mass called superphosphate of lime.

The outlines of the process are simple enough. You take, say, 620 lbs. of finely ground bones or other phosphates, add 240 lbs. of common sulphuric acid with a little water to replace the moisture driven off by the heat of the chemical action, and the result is 860 lbs. of superphosphate of lime.

In the insoluble raw phosphate, each part of the valuable phosphoric acid was tightly held by three parts of lime (hence called tri-calcic phosphate). The sulphuric acid has altered this little arrangement. This acid has a great attraction for lime, and promptly attacked and possessed two of the three parts of lime that kept the phosphoric acid imprisoned and useless. These two parts of acid and one of lime are now sulphate of lime, of which 3 lbs. are found in every 10 lbs. of the mixture called superphosphate. The phosphoric acid has now only one part of lime (hence called monocalcic) to look after it. In this form it can easily do its natural duty of being eaten by plants.

This duty is a most important one, for no plants can thrive without a sufficiency of phosphoric acid. And the acid must be in such a state as to be easily taken up.

Herein in its very virtue lies its danger. The acid, to be taken up by plants, must be soluble in water. Thus superphosphate is perfectly soluble, *i.e.*, melts like sugar for instance, in water. Consequently any great fall of rain easily carry it away. Worse than this danger even is abnormal fondness lime has for it. So if lime is present the soil, two parts of lime will at once seize on phosphate with its solitary lime companion, and conver into the old useless, insoluble three-part lime phosph (tricalcic). The two extra parts cannot seize on the phosph at the same time ; the first one does its work very quick the other takes a little more time, but effects its purpose aiding in the imprisonment none the less surely.

Now this little episode in the lives of phosphate lime explains a great deal. We remember a case wh a planter experimented in a large way, and most unsucce fully, with superphosphates. The fertilizer had not slightest effect on the plants. He wrote home to manufacturers abusing them roundly for the worthlessn of their wares. They asseverated that the superphospha were of the best, and enquired the exact methods of ap cation. Then it all came out. To dry the soft pulpy m before use, the indignant planter had mixed a large quant of lime with the superphosphate. Overjoyed at this chan the merry molecules of lime had promptly imprisoned phosphoric acid and rendered it useless for the time bei

So that when lime is used at all, it should precede application of superphosphate by six months at least, to g it time to be changed into carbonate by exposure to the soil and rain.

This then is clear. That a wish alone to dabble chemical fertilizers is not enough, if we desire to obtain fullest results. We must either ourselves know all ab their intricate little ways and methods of behaviour or— Why, we must pay some one to tell us !

NOTES.

Coffee hybrids. We commend to the careful tention of our readers the first of series of papers on the " Fertilisation of the Coffee Blosso by a well-known expert, who will be easily recognised his initials " J. C." The article will be found elsewhere

The American sieve test. The very gratifying victory substituting No. 26 for No. 16 sie in testing the teas imported to States has been entirely due to Mr. Blechynden, the Indi representative of the American Market Fund. He worked extremely well, and Ceylon men accord him f measure of praise for his success, which is their's also, course.

Vainghy and ash timber. Thus the *Produce World* :—" I recent number we drew attention enquiries of the English Coach Bui ers' Association and the Imperial Institute for a substitu for ash timber. *Planting Opinion* now suggests Vaing as a substitute. We should be very glad to receive samp of the same from Indian Planters, and to obtain informati here as to the wood's suitability for coach-building."

Ants and ashes. The following recipe for drivi ants away from coffee beds is sent the *Straits Times* from Kuala Lumpur :—" Dig where t

black ants are to be found, and sprinkle cold wood ashes as much as may be necessary. This will drive away the black ants, and will probably prevent the white ones from coming up." The ashes will not only drive black and white, but even red ants, and can be used to keep the little parties away from almost every object dear to their tiny hearts.

Good old "Mariawatta." The yield last year off this champion-bearing estate of Ceylon has beaten even its previous record. The whole acreage of the estate is 458½ acres, and the average yield ran out to 926 lb. made tea per acre. The acreage yield per acre for the oldest and best field, 101 acres, for the last fourteen years is 1,137 lb. Liberal manuring—town sweepings—of course accounts for a good third of the crop. Low country estates in Travancore and the Wynaad may run this grand record close in time.

High-priced Costa Rica coffee. Some time ago we rather startled our readers by drawing prominent attention to the possibility of a great improvement being effected in American coffee, owing to the introduction of European capital. The Sarapigni (Costa Rica) Estate Co. has already shown what can be done in that way by the fact of its last year's crop selling at an average of 96*s.* per cwt. This, too, with imperfect arrangements for curing, must be considered highly satisfactory.

Butterflies and tea. A wild story comes from a Calcutta paper:—"Many years ago, a case of butterflies was sent from Assam to England. A Professor of Entomology, on examining them, pronounced some to have come from China, but was told that such was not the case, as all had come from Assam in India. On receiving this reply, he remarked: 'If that be so, there must be tea in Assam, as such and such butterflies feed only on the tea plant.' This extraordinary statement was reported to the Court of Directors, who ordered enquiries, with the result that the wild tea forests of Assam were discovered!"

Tea seed oil. The sudden and utter collapse of the seed market has again turned the attention of planters, and especially those who grow tea only for the seed, to some means of utilizing the oil. This oil has a certain value, principally for burning. The cake of course would be valuable, to some extent, as a manure. We doubt much though if the proceeds from both oil and cake would repay for the cost of manufacture. Poonac at Rs.2-8 the Bengal maund does not leave much profit for tea-seed cake! The collapse of the market is important chiefly as showing the effects that the prospect of a permanently high exchange have on the industry.

Wood-ashes as a medicine. In the *American Naturalist*, Mr. Stahl, of Illinois, extols the virtue of wood-ashes as a medicine for farm animals, and says that used with discretion no other remedy is required to keep animals in full health. For swine he makes a mixture of wood-ashes, charcoal, and salt, and keeps it constantly before them in a large box having holes in the bottom, through which the animals work it out as they require it. He also speaks well of the mixture for horses, and in thirty-seven years of experience of farm-life has lost only one horse, and that through an accident. The ashes may be administered by putting an even tea spoonful on the oats twice a week; but he thinks it preferable to place a mixture of three parts wood-ashes to one of salt constantly before the animal in a little compartment at one corner of the feed-box. Mr. Stahl also has great faith in the value of wood-ashes when used as a fertiliser.

Plastering up seed. A new method of packing seeds and tubers is quoted from a French paper by the *Gardener's Chronicle*, which seems ingenious and practical. The method consists in moistening a little plaster and embedding the seeds, tubers, or rhizomes, which are to be transported in it. This plan has succeeded well for packing rhizomes sent from Japan, the roots of aquatic plants, the lengthened transit of which is always a difficulty. Enveloped in plaster, the plants, or pieces of plants, are in no danger; they cannot become parched and are kept in a condition of partial moisture. In Australia the method is also employed for the transport of butter. The butter is made up into blocks with rectangular surfaces, to which are pressed slabs of glass of the requisite size. The edges are covered with gummed paper for greater security, and the whole is covered with plaster to a thickness of a quarter of an inch. Plaster being a poor conductor of heat, secures the butter against the variations of temperature, and enables it to be kept longer than is possible under ordinary conditions of packing.

Odam's tea manure. This is a patent fertilizer much in favour just now in Ceylon. The guaranteed analysis is 18 to 20 per cent. soluble phosphate of lime; 4 to 6 per cent. undissolved phosphate of lime; 3½ to 4 per cent. of pure ammonia, and 4 to 5 per cent. of pure potash. Mr. Keith Rollo, Manager of the Wanarajah Tea Company, says of it:—"The results have been excellent, as tea has immensely improved and given remarkably heavy flushes, and when pruned two months ago there was magnificent wood to prune on, which means heavy flushes for another eighteen months at least."

The excellence of these manures has been certified by Dr. Voelcker, of London; Dr. Macadam, of Edinburgh, and others, including Mr. John Hughes, F.C.S., Consulting Chemist to the Ceylon Planters' Association. Messrs. Baker and Hall, the Ceylon agents (who advertise elsewhere), have already this season booked extensive orders for Hatton, Kalutara, and Wattawala. To these districts in a very short time fifty tons of the tea-fertilizer will be despatched. As an instance of what the manure will do, we are assured that on part of one estate the yield was raised from 300 lb. to 700 lb. per acre.

An ideal shade tree. An ideal shade for coffee, says a writer in an exchange, would be a continuous canopy of small-leafed trees with the branches some way off the ground for admitting the early morning sun, the light penetrating to the coffee beneath during the day. The *biliwara* (Albizzia odoratissima) would answer the purpose very well, but unfortunately it has not got much of a spread, and consequently in order to adequately shade coffee with it, it would be necessary to grow a large number of trees which would be harmful as the ground would be permeated with roots. The tree attains

a height of 80 feet in good situations with an unforked trunk of 30—40 feet. It is the best to coppice for fuel and lends itself to nearly every domestic purpose. The Albizzia Muluccanna is a very good tree. It has a good spread, the shade it affords is light, and another advantage it possesses is that the leaves close at night and admit the moonlight to the coffee when there is any. If retained too long, however, it runs a great deal to bole and the roots get a great hold of the ground. It is generally played out in about 20 years. It is a splendid tree in spite of these defects, and in order to derive the fullest advantage from it, relays of plants should be planted, and as they grow up, the older ones should be eliminated. In fact, all trees should be dealt with in the same manner.

The tea market.

Indians.—The market has been practically closed during the last week, says the *P. M. Review* of 1st instant, and transactions have consequently been of a limited character. However, with the opening sales on Monday next, comprising 25,000 packages, a good demand may be expected, as prices are reasonable and the stocks held by the trade are not excessive. There can, we think, be little doubt that prices for most grades have touched the lowest point of the season, and it will probably soon be difficult to follow the teas now obtainable, as many of those of recent shipments are of autumnal flavour. As usual there will also be a larger proportion of these teas coming forward later on, and as these can only be used sparingly by many blenders, owing to the appearance of the leaf, as well as to the risk of changing the character of their blends, it would appear to be quite safe to stock the earlier crop teas at current rates. The more recent advices from Calcutta report that the quantity available for this market will only be about the same as last season, and that future shipments will include a large proportion of very poor teas.

Of Nilgiri teas sold, Kodanaad, which obtained the respectable average of 8½*d.* for 53 packages, was the only estate represented. The Travancore average was 6·80*d.*; Arnakal (180p.) led the way at 7½*d.* with Penshurst (148p.) and Travancore T. C. B. A. (177p.) at 7¼*d.* a bracketed second.

East Indian shade-trees and leaf-disease.

Planters in Nyassaland are very anxious to get some of our better-known shade trees out, notably *the* new shade, *E. lithosperma*. But they are still more fearful of introducing leaf-disease, and the local Government are rigidly enforcing the regulations for the prevention of leaf-disease in Central Africa which prohibit the importation of seeds from India and Ceylon. We have more than once referred to this point. On recently appealing to Mr. Thiselton-Dyer, the Director of Kew Gardens, for his assistance in importing disease-free seed, no consolation was received in reply. In his report, Mr. Dyer says :—

"The coffee disease was introduced into Fiji through the instrumentality of tea seeds from Ceylon. Notwithstanding the splendid attempts made by Sir William MacGregor to stamp it out, it ultimately completely destroyed the coffee industry, which was the most promising planting enterprise in the colony. The Germans, by some unknown means, have succeeded in introducing the disease into their African territories. In the face of these undoubted facts it would, in my opinion, be the height of folly to run the smallest risk of introducing the disease into British Central Africa, where its presence would be an irreparable disaster. Knowing the mechanical way in which such work is carried out by native officials in India, I do think that any stipulation as to locality is of the smallest va Whatever was stated to the contrary, the first parcel of seed wo in all probability, come from a plantation reeking with disease. present request is the more unnecessary as, according to a co planter in Nyassaland who is well acquainted with coffee cultiva in Ceylon, a local African tree, *Albizza fastigiata*, is admirably ad ed for a shade tree for coffee. If this is not sufficient, the rain t or *Pithecolobium saman*, might be tried. The seed can be obtai in abundance from Jamaica, and this would be perfectly safe."

The coffee market.

Since our last issue, says *P.M. Review* of 1st instant, no pu sales have been held, and, in consequence, very li business has been done. The stocks are, indeed, of suc limited nature, consisting almost exclusively of comm and undesirable parcels, that there is no inducement buyers to increase their holdings. With the arrival of new crops there will no doubt be an improvement in demand, as the stocks in the country are generally c sidered to be much reduced, and some advance in values therefore, looked for. In the terminal market a moder business has been done, and prices first rose on the vari reports received from Brazil stating that the crop has b damaged by drought, but have since fallen upon a v decided increase in the daily receipts at Rio and San The market closes at an advance of about 6*d.* compared v a fortnight ago, after having been 1*s.* 6*d.* dearer.

Agricultural research in Java.

The liberal and up-to-date po that governs agricultural resea in Java is well seen by the pres flourishing condition of what are modestly called Buitenzorg Botanical Gardens. The institution, for i nothing less, is divided into nine divisions :—

"Division I. Herbarium and Museum.
„ II. Botanical Laboratories.
„ III. Agricultural and experimental garden (181 ac with Laboratory for agricultural chemistry.
„ IV. Pharmacological Laboratory.
„ V. Botanic Garden (145 acres) and Mountain Gar (77 acres and 700 acres of virgin forest) Laboratory.
„ VI. Office, Library and Photographic Laboratory.
„ VII. Forest flora collections.
„ VIII. Laboratory for the study of Deli Tobacco.*
„ IX. Experimental station for coffee.*

"The second division has special laboratory accommodation 8 foreign visitors, the institution acting, since 1885, also as an in national botanical station that has already been visited by a g number of foreign naturalists.

* The divisions VIII. and IX. work at the expense of private mittees of persons interested in the culture of Deli tobacco and coffee.

The staff consists of 27 Europeans and over 200 nativ As the *Ceylon Observer* says, the above points ou

lesson indeed to both India and Ceylon. What have we got in Madras, for instance? One or two tiny little botanical gardens on the Nilgiris and one at Madras. We have no research stations, and practically experimental cultivation is totally neglected. We do not blame Government for this. Far from it. Planters have representatives enough to voice their needs; it is entirely their own fault if a much-worried Government waits to be asked before it gives.

Jadoo fibre. We have received one or two leaflets on the nitrates of this patent manure when used as substitute for leaf mould. What we have not yet seen, but would very much like to, would be the results in the open of jadoo-manuring compared with "artificials" and cattle. We reprint a "certificate" from Mr. J. J. Willis, Superintendent of Experiments at the Laboratory of Sir John Bennet Lawes, Bart., D.C.L., LL.D., Sc.D., F.R.S., Rothamsted, Herts:—

HECLA VILLA, CARLTON ROAD,
HARPENDEN,
8th December, 1897.

DEAR SIR,

I have made a partial analysis of the sample you sent me, and the results show that the fibre is richer in organic matter and in nitrogen than the famous leaf moulds of Rambouillet and Mauripas, France. But while it does not contain so much organic matter or nitrogen as the Ghent heath mould, so largely used for growing Azaleas for market, yet it is richer in mineral constituents.

The data show pretty clearly that the reason of the great value of Jadoo Fibre rests in the fact that the fermentation of the organic matter renders the substance just sufficiently soluble to be readily acted upon by the mineral constituents—Phosphoric Acid, Lime, and Potash—naturally present, and assisted by that incorporated, so that the nitrification of the material goes on gradually, yielding up to the growing plant just enough nitrogen, but no more than it requires day by day, therefore minimizing the loss of nitrogenous plant food, and ensuring a lasting effect in the material employed.

I beg to remain,
Yours faithfully,
J. J. WILLIS.

It would have been interesting to have the analysis published, and not only compared with leaf mould of different qualities. However, we doubt not that Jadoo is an excellent fertilizer enough, but until its present absurd price is reduced, can see no future for it in this country. A factory in India would lower the cost by nearly half, and it would pay even then handsomely.

Banana figs and flour. Commenting on recent articles on the subject in this paper, the *Produce World* makes the following remarks:—

"Bananas and banana flour, as articles of export to London, are evidently attracting increased attention. A planter located at Saklaspur, in Mysore, has recently been asking the Editor of *Planting Opinion* whether there is any known instance of plantains having been profitably shipped in bulk to England, and also for instructions as to the best methods of preparing 'plantain or banana meal.' As to the shipping of bananas in bulk, unless sent on by the fast mail steamers, and then in cool chambers, we do not see much chance, as yet, of a profitable trade, especially in view of the large number of Jamaican bananas now on the markets. By fast steamers, however, India is practically no further from London than Jamaica, and if planters could induce the steamship companies to provide suitable storage, it ought to be possible to place bananas on the London market in good condition. Have the planters, through their associations, no means of bringing pressure to bear upon the companies to provide suitable means of carrying all kinds of fruits, both from India and Queensland?

"Banana figs are another form in which this fruit may be placed on British and Continental markets. When ripe, the fruit is gathered, thoroughly dried, and then pressed into boxes, as with the ordinary fig. Consignments which have hitherto reached England have often been packed into too large boxes; the most suitable size is the one used for ordinary figs. Care, however, should be exercised that only boxes of some white and flavourless wood should be used. Prepared and packed thus, a market could be found for banana figs.

"Bananas and plantains, however, must not be regarded as identical, for though apparently of the same family they have considerable points of difference. Flour made from plantains does not find favour in London, but banana flour is quietly effecting a footing. It is regarded as particularly good for food in cases of typhoid. As to the manner of its preparation, we would refer our readers to an article which appeared in these columns last October. With all respect to *Planting Opinion*, however, we would advise against packing the meal in tin-lined cases or air-tight canisters, as some amount of sweating invariably takes place during the voyage to England and mustiness results. The best way of shipping is to put the meal into thick sacks or barrels, after thoroughly drying. At present, Messrs. John Haddon and Co., Salisbury Square, are working hard to make this product better known and appreciated, both in England and on the Continent."

The difference between plantains and bananas is purely one of taste, of degree and not of kind, but here in India bananas and plantains both go by the same name, *i.e.*, plantains. It is obvious of course that in making banana figs, only the very best quality of fruit should be used. Banana flour is made from green fruit and figs from ripe fruit.

Planting diaries. We wonder how many of our readers attempt to keep a succinct detailed history of the working of the estates they own or manage. We do not mean of course merely the age of the different fields, or the records of crop or distribution of labour of the whole estate. We mean more than this by far. Except by the rough and ready methods of estimating by the eye, preserved in the oft so treacherous memory, there are usually no means of comparing the results of different styles of treatment. This is greatly to be regretted, as rough and inaccurate empiricism is the reverse of practical, and tends to progress of a sort that can scarcely be distinguished from stagnation. We advocate nothing complicated or theoretical. Simply, a detailed and careful comparative record of work and results. Every estate is divided for convenience in working into a certain number of fields. Some are usually treated in one manner, and some in another. But no attempt is made in noting down their respective differences in treatment and result. The consequence is that it is absolutely impossible for the great majority of planters to be able to prove, in a logical manner,

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton:—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Shencottah.

the superiority of any given treatment over another. This is, indeed, far from his thoughts. What, has he been a planter for the last fifteen or twenty years or more, and can't he prove to anyone's satisfaction that his favorite methods are the best? Do we mean to say that we won't accept his word? In reply, we merely point to a neighbour, of as great experience as his and as successful. His views on the subjects under discussion happen to be diametrically opposite. It is a little curious, isn't it? If our first friend is candid, he will admit, with a great deal of pressing, that after all his conclusions only hold good for his own estate, and that the exposure, soil, or something else must be different in his neighbour's tote. Press him still further, and point to fields in both gardens identical in all respects, and he will say: "Well, I do my best. No man can do more." As a matter of fact he doesn't do his best, *i.e.*, the best of which he is capable. He does the best according to his lights, but his lights may not be of the best.

What he ought to be able to say is somewhat after this style. These two fields are about the same aspect and soil. I have treated one in a certain fashion for the last ten years or so. My methods with the other differed in so and so. The results in crop compared with each other are so and so. Here are the records.

Ah, those records! How neglected they are, and yet how valuable. The lessons they would teach would be irresistible, no guesswork needing to be backed up by profuse talk simply reiterating the arguer's impressions. Some few have kept them religiously for a number of years, and these are, without exception, the most successful estates we know of in the district. Toes are bound to get trodden on here and there, but we mean to keep on hammering at this subject for some weeks yet, so we will apologise in advance.

LETTERS TO THE EDITOR.

MANGALORE TILES: COST OF.

SIR,—Can any of your readers work out the comparative cost per 100 square feet of "Mangalore" and the usual country tiles, reckoning in the amount of timber required for each?

With country tiles @ Rs. 5 per thousand (using 2,000 per 100 square feet), and reckoning cost of rafters, reepers, mats, &c., the cost per square (*i.e.*, 100 square feet) runs about Rs.25 to Rs.30, according to quality of timber, reepers, &c.

What distance apart should rafters be placed for "Mangalore" tiles, and what thickness ought the purlins to be fixed?

For country tiles a half-rafter ($2\frac{1}{2}'' \times 2\frac{1}{2}''$) is used every six inches. Then reepers (bamboo Rs. 6,100; gum Rs. 30 per 100) 2 inches apart. Then mats (about 9 per square) and, lastly, tiles.

As far as I can make out, country tiles are a trifle more expensive than "Mangalore" tiles and not half so nice.

TILE.

"SOIL RENOVATION."

SIR,—In the article on Soil Renovation in *Planting Opinion* of the 8th instant, there is an important error which, as it is not clear from the context, I should be obliged if you would allow me to point out in your next issue.

It appears as follows:—"We have the surface soil converted into humus containing one-half times as much nitrogen as cattle manure."

For one-half please read *one and a half*.

The quantity of nitrogen in cattle manure I reckoned on the basis of Professor Wolff's well-known analyses of farm-yard manure, and calculating on that basis, the worm-castings un*E. lithosperma* trees will be found one and-a-half times as r as cattle manure.

ARIENKOW, SHENCOTTAH, *14th January, 1898.* B. NELSON

GENERAL ARTICLES.

THE NEW TEA-PLUCKING MACHINE.

INVENTORS PLEASE NOTE!

A READER has been attempting to explain to us his ide on what he says is bound to be the tea-plucker of t future. Being no mechanic himself, he gives his ide free to the inventor who may happen to read this par graph. He starts by endorsing the condemnation of the patent pluckers in the market, which are based on entirely wrong principle, *i.e.*, shearing the bushes inste of plucking the flush separately. His idea is to imita the hand in a way a little difficult to describe without profuse use of cuts. However, we shall make an attemp Imagine a hollow tube, some six inches in length, a about half inch diameter. At one end of the tube is knob, which acts on a strong spring. On the knob bei pressed by the finger, a sort of forceps made of wire shoots o a couple of inches and closes on the stalk of the flush in t same manner as the finger and thumb do. On the spri being released, the forceps springs back, and in doing executes two movements. One is to break off the flu by a sudden bending to one side, and the other is to thro the picked flush into a small open basket fixed on the tu by a second reverse movement. Having accomplish this difficult and seemingly complicated feat, it retires the tube. There are six or more of these tubes fixed in row together, and the machine is manipulated with bo hands. One hand holds and points the plucker, a works on the knobs.

To the above we would add a few remarks of our ow The action of the forceps emerging from the tube, openi to seize the leaf and then closing to break it off, a finally retiring is exactly the same as that of the "Eagle automatic pencil. So there is no impossibility to perfor so far. It is perfectly feasible to pluck the leaf in th manner. It is more difficult to devise the throwing of t leaf into the basket. Perhaps this is not really necessar though of course more perfect. The forceps might sta permanently out of the tube and retain its flush until the six forceps were provided. Then a slight simultaneo pressure on all the knobs would make them to release the burden in the picker's cloth.

A simpler plucker still might be devised, or rather pair of them. They would consist of a single hollow tu with a single pair of forceps, which would simply break the flush and deposit it automatically in a receiving wi basket beneath attached to the plucker.

Talking of patent pluckers, the Indian Tea Associatio or the Ceylon Planters' Association, or both combine might well offer a substantial prize, say, of five thousa rupees, for a really satisfactory patent plucker. If one the conditions were that the plucker should pick double t usual kanak, the resulting saving to the community would immense. Allowing that leaf can be picked at the l

rate of one pie per pound, the saving per pound of tea would be two pies. The total production of British-grown tea may be put at 250 million pounds. This, at two pies per pound, would mean a saving of 2,60,000 rupees. Yet if only half the crop could be picked by these patent pluckers, over a lakh of rupees would be saved, allowing the balance for the cost of the machines. As a matter of fact, the average cost of plucking leaf is about double the amount we have mentioned.

The fact is that it is almost impossible for the planting community to regard itself as a trading corporation. It will not venture to lay out a few rupees in offering such rewards as suggested because of the inability of each unit of the community to regard itself as a unit, and nothing more. Five thousand rupees seem a lot to pay for an invention, thinks the unit. But *he* is not asked to pay all that himself. His share will be only a rupee or two. Not that he sees it however.

HOW WATER ACTS IN PLANTS.

The most interesting facts of science are often passed over with carelessness, merely because they are supposed to be well-known commonplaces. It is thus with the function of water in the life of plants. Knowing that plants need water more even than human beings, most think there is nothing more to know.

Nothing more to know! If we could trace the complete history of the functions of water in plant life, we should have explained perhaps 99 per cent. of all that is now so obscure. Plants are almost all water. Some, like cabbages, onions, lettuce, contain up to 98 per cent. of water; green clover contains 86 per cent., while even dried straw or cornstalks contain 10 to 15 per cent. of water.

It is very clear that water must be taken up in large quantities by the plant. But how is it taken up, by its roots or its leaves? A certain proportion of plants, mostly of a low order, absorb water both ways. A large section only make use of their roots. How does the water travel up the plant; how can it ascend from the lowly roots of a giant of the forest to the topmost leaf on its summit? What force is used to bring this about?

It was at first held that capillary attraction was sufficient, but certain curious experiments disproved this theory. Capillary attraction is, by the way, nothing more than is daily shown in the action of ink on blotting paper. To revert to the experiments. The cut stem of a vine was fitted into a tube containing mercury. The force of the sap movement raised the mercury 32½ inches, enough to raise water 36 feet high. The pressure of the atmosphere only raising mercury 30 inches, the force of the sap upwards was considerably more than the atmospheric pressure.

To dwell for a moment on this flow of sap. It is often found useful to man. In Java certain plants (*cissus*) are used as fresh-water springs, and in many parts of India and South America similar plants are found. The American aloe (*Agave americana*) yields a sap which, when fermented, forms the well-known American intoxicating drink of *pulque*. The flow of sap being continuous for some months, a single plant will give over ten gallons of this liquid.

But to come back to the question of the motion of the sap, and how it takes place. We all know that plants transpire a great deal. That is, that by means of the pores on their leaves they pass out into the air a large quantity of moisture. We shall dwell on this process a little further on. The drier and hotter the air, the quicker does the transpiration go on. Well, the water brought up into the plants by the roots is not pure water by any means. It holds a great deal of chemical elements all melted up in it. The plant is formed of tiny cells, each adjoining but distinct from the others, and the separating walls are of the finest tissue-like membrane imaginable. Well, the cells near the transpiration points, that is to say the leaves, are continually getting their water taken away by transpiration. The sap they contain is apt to get, we may say, like a very thick soup. The cells below and nearer to the roots contain thinner soup, and by a certain chemical law, liquids of different density (or thickness we may say) separated only by membranes have a power to mix themselves up so as to render the liquids on both sides of the membrane of one quality. So that there is a continual exchange of liquids between the cells of the plant, resulting in a strong upward flow of sap from the roots. A very simple and well-known experiment can be used to illustrate the argument. Take a basin of salt water and a bladder of pure water. Lay the bladder in the basin. After a time, take out the bladder and taste its contents; they will be found to be salt, but not so salt as the water of the basin formerly was. In other words, the mixing of the liquids will take place very nearly as easily as if there was no membrane to separate them.

This insignificant-looking law is the reason of the upward rush of sap from the roots, aided of course by transpiration.

Let us return to transpiration. First, to prove that it takes place. Place a growing plant under a glass cover. In a few minutes dew will be deposited on the inside of the glass. This can be hastened by dashing the outside of the glass with cold water. Having proved that plants do transpire, let us see how they do it. They transpire by means of minute transpiration pores or *stomata*, which exist both on the under and upper surface of the leaf. Their number varies considerably on the leaves of different plants. Succulent plants have remarkably few. One square millimetre of a leaf of a cabbage has been calculated to contain 400 stomata on the upper surface of the leaf and 700 on the under side. A square inch of a lilac leaf may contain 120,000, a linden leaf 1,000,000, and the under side of an oak leaf over 2,000,000. Their size varies. They are largest in orchids, lilies, and grasses, and smallest in olives and fig trees. As the leaf surface of most plants is considerable, the amount of water entering the air in this way, and consequently having to be replaced by being absorbed by the plant's roots must be enormous. According to a calculation by an American botanist (the late Asa Gray), a certain elm tree produced every year 200,000 square feet of surface (about five acres), whereas the actual space of ground it covered was only about a fiftieth part of this in extent. It has further been calculated that an oak tree, within a period of six months, transpired during the day

Advertisers are notified to send all advertisement matter and answers to advertisements direct to Manager, this paper, 3, Esplanade Row, Madras

Correspondence and matter for publication to be sent to Editor, this paper, Coonoor.

time eight and a half times as much water as fell in the form of rain on an area equal in circumference to the tree top. Calculations have been made as to the amount of water given off by different plants. Thus an old experimenter found that a sunflower, with a surface area of foliage amounting to about 40 square feet, gave off twenty-two ounces of water in twenty-four hours. A maize plant again was observed to transpire in about two and a half months' time about thirty-six times its weight of water; while an acre of grass land transpired more than thirty hogsheads in a day. Perhaps the best conception of the amount of water transpired by different plants may be afforded by the statement that in a series of experiments carried out on the common agricultural plants, it was found that for every 1 lb. of dry tissue formed, a transpiration of from 233 to 912 lb. of water took place. The plant which transpired the least quantity was maize—viz., 233 lb.; while that transpiring the most was rape, 912 lb. Mustard, barley, and oats all transpire large quantities. About 350 lb. may be taken as an average for the common agricultural plants. The dangers of allowing growth of weeds in dry weather is thus easily understood.

FERTILIZATION OF THE COFFEE FLOWER.

[BY "J. C."]

A GOOD many planters who will recognise the above initials know that I am keen on the crossing of coffee. Wishing them and others to be equally keen in a work which may eventually lead to the advantage of the whole planting community, I venture to offer a few hints as to how the details of the crossing may be put in motion. The process of fertilization, if confined to individuals of the same species, will only result in producing "varieties" of the individuals concerned. But when it is extended to different species of the same genus, then an intermediate class of plants called "hybrids" are produced. As this may not be quite clear to all, I shall give a practical illustration. When two bushes of *C. arabica* are growing near to each other and flowering simultaneously, they will be observed to attract many insects of the winged class. It is a marvel where these insects come from in such numbers and at such short notice. But there they are the whole day, hurrying to and fro from one bush to the other until, perhaps, every newly-opened flower has been visited. Now, although these insects have been most industrious in their own interests, collecting food and building material, the chances are that they have unconsciously rendered a signal service to the coffee also by carrying pollen from the flowers of one bush to that of the other. If they have done this inadvertently or otherwise, the insects have effected cross-fertilization to the extent of producing varieties, or new forms of the two bushes concerned. By excluding the services of the insects altogether, the same results, and even more effectual ones, can be secured by delicate manual operations. But of this further on. The difference between the fertilizing work of insects and that of man consists in its being promiscuous and haphazard in the one case and systematic in the other.

Now if individuals of two distinct species, such as *C. arabica* and *C. liberica*, were to blossom together in manner described above, exactly the same activity of in life would be observed, with, perhaps, similar results, that in this case the progeny would be more than a "varie it would be a "hybrid." Planters know that year a year their nurseries are stocked with seedlings raised f local seed of which a small percentage appear to be varieties, or at least different from their fellows. T know also that nature is herself responsible for variation. If the life history of a number of seedlings carefully traced, it would be found that while a few diff in the form, size, and texture of the leaf, others in the and quality of the fruit or habit of growth, the major would be nearly identical with the prevailing variety on estate. This is all right where the prevailing strain is g But where the product for which a plant is cultiva shows signs of exhaustion, or has become deficient in qua or quantity, the strain is said to have "run down," an all such cases too much individualism in reproductio undesirable. It is in all probability to prevent this runn down of strain or breed that nature insists on c fertilization.

Coffea arabica, or Arabian coffee, of which there are sev well-defined local varieties known by such names as "Chic Coorg, and "Nalknad," has been almost exclusively cult ted in this country from the time the industry was star and it is only within recent years that one or two varieties and species have been introduced and cultiva on the estates. This fact will explain the absence hybrids over such an extensive area, there being material to make hybrids from. Yet, within the past years, some hybrids have made their appearance, sho following the introduction of Liberian coffee, a distin new species. And, barring the fact that two distinct spe have been placed in juxtaposition to each other, hybrids are the work of nature. But in the instan referred to, man must get the credit of having materi helped nature by providing a new species for the latter work upon.

If he would, therefore, do more in this direction, chances are that worn-out strains of coffee would soon replaced by better kinds.

This leads me on to the suggestion that approved variet and new species of coffee should be freely introduced fr other countries. The field for experiment would then much widened, as planters would have sufficient mate to work upon.

The cultivated forms of coffee in different parts of world are already so far advanced of the indigenous wild bush that it would probably be mere waste of effort bring the latter into experiments, the object of which is secure further improvement in productiveness and quali Collections of species and varieties should, therefore, be c fined, in the first instance at least, to well-known j already in cultivation. These I shall leave the plan being the best judge, to select for himself. Now suppos that some enterprising planter has already secured suc collection of coffee-bearing plants, how is he to dispose them to the best advantage? This is a question that I sh endeavour to answer in my next.

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

THE "GREAT" RUSSIAN TEA PLANTATIONS.

THE following is an excerpt from a very interesting letter written by a Ceylon Planter, Mr. R. V. Webster, to the Island press.

The most noticeable fact is that, until locally-grown tea is taxed in the same way as tobacco, oil and other productions, it will pay the grower handsomely. Mr. Webster thinks it highly unlikely that the tea will remain untaxed for long :—

RUSSIAN PLANTATIONS.

Calling on the manager of Mr. Popoff's retail establishment, I was astounded to learn that even he was not admitted to the plantation. He also informed me that the Minister of Finance at St. Petersburg, after driving to the plantation, was not allowed to enter it. The Svostchiks demanded double fare to drive to the plantation, as the snow in parts was deep, and they require four horses, so I decided to wait till the following day, when I took train to Chakva and visited the first Russian tea plantation, which I now discovered was started by Colonel Solovitzoff in 1885. During my stay at the Caucasus I visited the Solovitzoff plantation, which has 100 acres of tea, Popoff's plantation with 250 acres, and the Imperial Domains plantation with 150 acres. Colonel Solovitzoff, a retired Officer of the Engineers, was the pioneer tea planter in Russia. In 1885 he planted 36 trees that were imported from China; with the seed gathered from these 36 trees, 250 out of the 500 acres in the Caucasus have been planted. The much prized seed bearers stand three feet high, and are to be seen in front of the factory; that they will each year bear seed in abundance they may be assured, as they are a jât known only too well at great cost to many in India and Ceylon. I went through a clearing in its seventh year and found it not as far advanced as tea in Ceylon or India in its third year. This is partly due to the short summer, bad seed, and strong winds from the sea to which all the plantations are exposed.

MR. POPOFF'S PLANTATION.

Mr. Popoff has his plantation closely guarded. On arrival at the gate three Circassians, each armed with two swords, three pistols, and a rifle, presented themselves and demanded my permit. Handing my card of admission through the bars, two entered a hut to study the document, while a third kept guard. After some fifteen minutes, when they had satisfied their curiosity, one ascended the hill to the Superintendent's bungalow; another fifteen minutes in the sleet, and the messenger returned with orders to open the gate, and for the first time a tea planter, and a British subject, entered the plantation which is kept such a profound secret. On ascending the hill I met the Superintendent, who showed me round the plantation, which has cost over 800,000 Rbls. (£82,000 sterling). It reminded me very much of the hill paddy-fields in Ceylon, as all the plantation is laid out in terraces five feet broad, the cost of which must have been very great, as the land in parts is steep. I saw tea trees from India, Ceylon, Java, and China, all of which looked well, notwithstanding the two feet of snow which lay on the ground, and the severe weather which had set in unusually early this year. Only a small area is planted with seed from India and Ceylon, and this has been condemned by Mr. Popoff. Perhaps his Chinese tea-maker thinks the leaves too long!

MR. CHINAMAN.

The Superintendent has no experience in tea, but informed me he is learning the work from their head Chinaman. This gentleman was brought from China and draws the nice sum of £50 per month. Along with him are ten other Chinese who, from all accounts, draw salaries that will enable them in a few years to return to their country and live on the fat of the land. Last year they imported 6,000 lb. of tea seed from China, out of which Mr. Popoff raised 49 plants. Mr. Chinaman may be counting on repeat orders till they raise the required number of plants!!

THE CAUCASUS.

In Odessa I was told that a large area suitable for tea was to be found South East of the Caucasus near the Caspian sea; but from what I have seen, and on what I believe to be reliable information, I report as follows :—South-east of Caucasus, south of Baku, and near the Caspian sea there is a mild climate and fair soil, but as there is little or no rain, and all the year round is subject to violent wind storms, it would be impossible to grow tea. On the East coast of the Caspian sea there is poor soil, no rain, and in summer violent hot wind storms that dry up all before them. On the Caucasus and to the north of Baku the winter has proved too severe. Last year out of the 5,000 plants put out near Tiflis not one survived to see the spring. South-west of the Caucasus, on the coast between Soukhoum and Batoum, there are about a hundred thousand acres where it would be possible to grow tea, but at no part is it more than three miles from the sea, and in many parts the mountains are very steep close to the sea. The soil is good and rainfall plentiful, and in winter there is snow and sometimes twelve degrees of frost. In summer they often have strong winds with hail which does much damage to the tea. From the 1st of April to the end of September the bushes will sprout, but after July the flush is checked by winds and hail. Tea of the right jât planted in the shade might in the eighth year give 200 pounds per acre; with labour at 1s. 6d. per day, I fail to see where the profit would come in for the grower even with 1s. 10d. per pound duty in his favour.

THE GOVERNMENT PLANTATION.

The latest addition to the Government plantation is 50 acres, planted with seed: the trees from which will never give 100 lb. of tea per acre. The cost of opening the land, seed, planting, and upkeep for first three years was £5,750 sterling, which is equal to £115 per acre. To this must be added the cost of land £10 per acre and Superintendent's salary! The Superintendent's estimate for this clearing is as follows :—5th year 60 pounds of tea per acre; 6th year 90 pounds per acre; 7th year 130 lb.; 8th year 200 lb.; and 9th year 250 lb., for which he hopes to get 3 Rbls. (6s. 6d.) per lb. It is possible that he may obtain his estimate for the first two years, but I am very certain he will be sadly disappointed in his returns for the following years, as also the price he will realise. At 3 Rbls. per pound, the Russian tea-grower would have a nice profit, but when he comes to realise 1 Rble. 8 Kp. (2s. 4d.) per lb., he will find the balance on the other side.

So India and Ceylon may count on Russia as a good field for their increasing supply.

P.S.— Since writing the above, I have received a valuation from Messrs. Gow, Wilson & Stanton, of the tea Mr. Popoff gave me while in Moscow from his plantation in the Caucasus, "6d. per lb." This confirms the valuation of my friend in Odessa.

DISTRICT ASSOCIATION.

SHEVAROY.

PROCEEDINGS of the monthly committee meeting of the Shevaroy Planters' Association, held in the Victoria Rooms, Yercaud, on Monday, the 10th January 1898, at 10 A.M. *Present* :—Mr. J. C. Large, Mr. H. W. Leeming, Rev. J. M. Kempf, Mr. C. Rahm, Mr. C. G. Lechler (*Chairman*), Mr. R. Gompertz (*Honorary Secretary*).

1. Mr. Large's letter *re* small change, which stood over from last meeting, was again read, and the Honorary Secretary informed the meeting that, in reply to his reminder, the Collector had stated that the matter was still pending. *Resolved* that the Honorary Secretary be requested to address the Collector again, and to suggest that, until the matter is settled, he should be pleased to arrange to send up a larger supply, both of rupees and small change, as there has been greater difficulty since receipt of his letter, No. $\frac{887}{B \& G}$, dated 5th July 1897, than there has ever been before in cashing notes at the Treasury, and particularly in obtaining small change.

2. *Read* letter from Mr. C. G. Lechler, suggesting that two vaccinators be sent up to these hills. Resolved that Mr. Lechler's letter be forwarded, through the Collector, to the District Surgeon, with a request that he should be pleased to comply with the suggestion made.

3. *Read* letter from Mr. Leeming, complaining that his name board had been torn down some time in November, and that, though he had written to the Deputy Tahsildar, who had issued orders about it, nobody had been to him to make enquiries. *Resolved* that the letter be forwarded to the District Superintendent of Police.

4. *Read* letter from Mr. Leeming complaining of non-execution of certain warrants taken out by him. *Resolved* that Mr. Leeming be requested to furnish all the details he can for Honorary Secretary to forward to the District Superintendent of Police.

C. G. LECHLER (*Chairman*).
ROBERT GOMPERTZ (*Hon. Secy.*)

PROCEEDINGS of quarterly general meeting of the Shevaroy Planters' Association, held in the Victoria Rooms, Yercaud, on Monday, the 10th January 1898, at 2 P.M. *Present*:—Mr. E. Dickins, Mr. R. A. Gilby, Rev. J. M. Kempf, Mr. J. C. Large, Mr. H. W. Leeming, Mr. T. B. Nicholson, Mr. S. M. Pritchard, Mr. C. Rahm, Junior, Mr. W. Rahm, Mr. C. D. Ryle, Mr. B. Short, Mr. F. Short, Mr. C. G. Lechler (*Chairman*), Mr. R. Gompertz (*Honorary Secretary*).

1. Notice convening the meeting was taken as read.

2. *Read* and confirmed Proceedings of Committee Meetings held on the 1st November, 6th December, and on this day.

3. *Read* Proceedings of the Court of the District Magistrate of Salem, held on the 7th December 1897, *re* Mr. Rickett's complaint against the Tahsildar. *Recorded with satisfaction.*

4. *Read* Circular letter from the Secretary of the U. P. A. S. I. *re* employment of an Agricultural Chemist, together with an application for the post from a Mr. Drysdale Turner, and the list showing the amount which members of this Association are willing to subscribe, and the number of analyses they are likely to require during the year. *Resolved* that, in the opinion of this meeting, it would not be desirable to join the U. P. A. S. I. in engaging an Agricultural Chemist for the whole of Southern India, but that the Honorary Secretary be requested to write to the Honorary Secretary of the Nilgiri Planters' Association, enquiring whether they would allow us to join them in procuring an Agricultural Chemist for the two districts; and, if so, on what terms.

5. *Read* letter from Mr. Leeming stating that the special Constables, appointed for the prevention of coffee stealing, had not visited Scotforth Estate for about a month. Several of those present, *viz.*, Mr. Kempf, Mr. Large, Mr. W. Rahm, Mr. E. Dickins and Mr. T. B. Nicholson, made similar complaints, about which they promised to write to the Honorary Secretary, who will then address the District Superintendent of Police on the subject.

6. *Read* correspondence about lady-birds. *Resolved* that the Honorary Secretary be requested to endeavour to collect the amounts promised for transmission to the Secretary, U. P. A. S. I.

C. G. LECHLER (*Chairman*).
ROBERT GOMPERTZ (*Hon. Secy.*)

W. MADRAS.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (January 7, 1898) says:—Public sales were resumed last Tuesday after a fortnight's interval, and the moderate supplies brought forward met a fair demand at unchanged values.

About 400 bags new crop East India attracted good competition and sold at steady prices, whilst one or two favourite Home Trade marks realised full rates.

Columbian formed the bulk of the Central American offered and was mostly disposed of at rather irregular prices.

Futures show a fall of ⅛ on the week in consequence of rather larger receipts and a decline in the Brazilian exchange: at the close however the market is steady.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending January 5th, 1898, says:—Bank rate 3%. Bombay Exchange closes at 1s. $3\frac{1}{16}$d. Brazil Exchange $6\frac{3}{32}$d. Rupee paper $3\frac{1}{2}$ % $62\frac{1}{2}$. Silver $26\frac{3}{16}$d. per oz.

Public sales were resumed yesterday, the moderate supplies catalogued selling well for all good and fine qualities, whilst ordinary and common continue about steady but difficult of sale. New crop East India and Costa Rica have again realized full values. Brazil markets are very quiet.

Daily receipts averaged 10,800 bags in Rio and 14,500 bags in Santos.

Futures close flat at about 1s. to 1s. 3d. per cwt. decline, viz.:—Good average Santos in Havre, March delivery, fcs. 37.75, in Hamburg pf. 31½, and No. 7 low ordinary Rio in New York $5.80.

To-day's London official quotations are:—

	Jan.	March	May	July	Sept.	Dec., '9

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 11th February, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nilgiris.

COONOOR, *2nd February.—Weather.*—Two or three spells of slightly rainy weather lasting only a day or two each, so far, this year. Everything is very dry, in consequence of failure of North-East Monsoon. Frost severer now; cold in the early morning is intense. *Crops.*—Coffee still coming in slowly. Wood looks grand for next year. Tea being pruned. Grain still high. *Plant-diseases.*—None about, if one excepts the damage done by porcupines to tea. It is lucky indeed that coffee does not attract these fiends. *General Health.*—Indifferent, touches of liver among Europeans being the most noticeable. *Labour.*—Ample enough.

Coorg.

POLLI BETTA, *27th January.—Weather.*—Clear and chill with high east wind. Last night, about 10 P.M., cold high wind blew strongly from east as if bringing up a storm, but the star sky was perfectly clear. Eclipse seen in ideal weather: not a speck of cloud anywhere. *Crops.*—Stripping continuing. Felling a little short of estimates. *General Health.*—Some improvement, but fevers still very prevalent.

POLLI BETTA, *2nd February.—Weather.*—Fine and cool; wind only occasionally. *Crops.*—Stripping still going on in parts. Finished in others. In few cases above estimates. In most slightly under. *Public Health.*—Great improvement has taken place since last report, though there is still some fevers and bowel-complaints about.

NOTES ON ANIMAL MANURES.

IT is needless to say that animal manures differ very widely in their manurial value. This value, which is usually based on the percentage of nitrogen they contain, has a direct connection with the food they eat and the mode of life pursued. Thus, the dung from an animal that is being fattened for slaughter, contains a great deal more nitrogen than the dung of an animal in hard work, or giving suck to its young. The explanation is simple. A fattening animal needs comparatively little nitrogen to build up its fleshy and fatty tissues; hence a large proportion of the nitrogen in the food passes out undigested in the dung. A milch cow, on the other hand, requires a large quantity of nitrogenous food to enable the secretion of milk to take place. Hence a portion only of the food nitrogen is passed in the dung: the remainder is partly in the milk and partly stored up in the tissues to replace the natural waste. This natural waste is strongly marked in the case of draught animals, whose working energy depends of course altogether on the nitrogenous and carbonaceous fuel or food they consume. Every 100 lbs. of milk, by the way, contain $\frac{1}{4}$ lb. potash, $\frac{1}{5}$ lb. phosphoric acid, and $\frac{1}{2}$ lb. nitrogen.

As regards inorganic matter, so-called, like the various phosphates, potash, lime, sulphur, magnesia, etc., it may be said that the great bulk is passed out unaltered in the dung.

The proportion that dung has to the food consumed varies a great deal. With horses about 47% of the food is passed out as dung, calculating both on their dry weight. The amount of nutriment that still remains undigested in dung is very considerable, as may be shown by a very curious practice obtaining in some rural districts of Norway. In long winters, when the supply of fodder runs short, it is the custom to shovel out the contents of the horse-stables carefully spadeful by spadeful on the snow. After a short time, cattle are allowed access to this curious food, which is eaten greedily. The food being twice digested, it is evident that the second lot of manure is worth almost nothing.

Cattle-dung is still held in most countries of the utmost importance. In Saxony, where wheat is largely grown, vast herds of cattle are kept to produce the manure needed. It is true that dairies are also established in connection therewith, but take quite a secondary place. The milk or butter may be sold, or it may not; but as long as the manure is supplied, the Saxon wheat-farmer is content.

As we have already observed, the value of animal manure depends closely on the quality of the food consumed. Of the usual foods given to cattle, cotton seed meal is by far the richest in nitrogen,—one thousand pounds containing 70 lbs. against only 1½ lbs. in turnips. Malt sprouts, 37 lbs., and clover hay, 21 lbs., come next. Wheat straw com very low on the list, containing only 3 lbs. of nitrogen p 1,000 lbs. In phosphoric acid, cotton seed meal is aga first, with wheat bran a good second, and malt sprouts indifferent third. In potash, also, cotton takes the lea closely followed by malt sprouts and clover hay. T general manurial value of each food may be expressed numbers, taking turnips at ·67. Cotton seed meal lea with 18·39, malt sprouts is second with 10·64, while whe bran is third with 8·52.

Young cattle, needing all the phosphates and nitrog they can get to form their bones and flesh tissues, natura leave their manure almost destitute of these two constituen

The dung of flesh-eating animals is of course very ri in nitrogen, while that of mixed feeders—like men, poultr swine—is also of a high quality. As we have shown the above, food controls almost wholly, other things bei equal, the value of dung.

Of liquid and solid excreta, the former is generally mo valuable, as it is without doubt the most soluble. It interesting to note that there is more solid matter per d in human urine than in fæces.

The changes that cattle-dung undergoes when stored, exposed in the field, are curious. Thus, in a well-knov experiment, a heap of manure 3 to 4 feet high, weighi 14,300 lbs. when fresh, and 3,975 lbs. when dry, bei exposed for a year to the influences of the weather, w reduced in bulk to 1 foot in height, while its weight w 6,730 lbs. moist and 1,360 lbs. dry.

The percentage of nitrogen before and after exposu was as follows:—

Nitrogen.	*Fresh.*	*Exposed.*
Soluble	... ·63	·30
Insoluble	... ·86	1·70
Total	... 1·49	2·00

The old manure has lost considerably in its percenta of soluble nitrogen, though it is richer in insoluble nitroge The total loss of nitrogen is nevertheless very considerab For if we reckon it out, the total nitrogen contained in t exposed manure only amounts to 2·73 lbs. against 6·60 l contained in the heap of fresh manure. Weight for weig however, old manure contains more nitrogen than wh fresh, though it is poorer in the soluble nitrogen, which the only one worth considering. It is sufficient to point o the huge loss of nitrogen that takes place when dung exposed to the weather, more than half being lost in t course of a year. In the planting districts, where t rainfall is so abundant, the loss would be even greater.

NOTES.

Exports of tea. The total sailings of tea fr Calcutta from the 1st April 1897 31st December were 130¾ million against 128⅛ m. t previous year. This was divided among a number different countries, first of which, of course, comes Gre Britain with 118½ m. against under 116½ in 1896. Austr asia took 5¾ m. against 4⅘ m. in 1896 and almost 5¾ m. 1895. America shows a falling off in direct shipments, bei 2 1/10 m. in 1897 against nearly 2½ m. in 1896. Ceyl

exported almost 108¾ m. from 1st January to 21st December 1897 compared to 102½ m. in 1896 and 91¼ m. in 1895.

Drought and coffee. One of the greatest difficulties which beset the path of the Nyassaland planters is the insufficiency of their rainfall. To conserve moisture, therefore, is one of their most urgent questions. Among other methods, excellent in themselves, is recommended trenching. We suppose by trenching is understood the usual system of digging continuous trenches between each row of plants, though we are not quite certain if this be so, for the *Central African Times* talks of *light trenches* being useful as a mulch. If light surface cultivation is meant, our contemporary has hit the right nail on the head, except as to the time this operation should be performed. Light surface cultivation can, and should, be undertaken in the driest weather. Otherwise the soil will "pack" and induce the very flow of moisture upwards, which it is desired to avoid.

Pumpkins for milch cows. Those who dabble in the dairy business may be interested to know that, in reply to an enquiry, Professor W. A. Henry, of the Wisconsin Experiment Station, says in Hoard's Dairyman :—"The pumpkin is a splendid feed for dairy cows in the fall, and our dairy farmers cannot use them too liberally. The dairy cow likes variety, and pumpkins can be grown so easily, and yield so well when planted by themselves, that a prudent dairyman will not forget this useful adjunct to his usually rather short list of feeding stuffs. The pumpkin, containing much nourishment, and being very palatable, tends to produce a large flow of milk. The seeds of the pumpkin, are said to increase the action of the kidneys, and I think the statement entirely reasonable. It is well, therefore, in feeding pumpkins in quantity, to rid them first of seeds, which can be done easily and rapidly."

Agricultural chemistry in Nyassaland. In a recent number of the *Central African Times*, we notice a strong leader headed "Wanted an Agricultural Chemist." The article was based on Mr. J. A. Harris's speech on scientific investigation at the last U. P. A. Meeting at Bangalore, which speech is reproduced in full by our contemporary. The need for scientific assistance in Nyassaland seems even more urgent than in South India : "Owing to difficulties in the way," says the *Central African Times*, "it is practically impossible for a man to come out here, and after putting in (*sic*) his plantation and working up his place, depend upon getting regular returns. . . . It is proved beyond a doubt that coffee will grow and bear crops of 3 to 6 cwt., but the plant gets easily exhausted. . . . . All we require is reliable help to enable us to *prolong* the bearing period of the plant." Very sound and sensible advice without doubt, but to base it on what South India is going to do, reads just a little funnily in the light of what has passed since that interesting speech by Mr. Harris was delivered.

Mr. Bamber on the Davidson Tea Roller. It will interest many of our readers to know that Mr. H. Kelway Bamber, who is already well-known to Tea Planters as an authority upon all matters touching the manufacture of tea, was amongst Mr. Davidson's visitors when he was showing the model of his roller in London and Mr. Bamber has since then expressed it as his opinion that the rolling motion given to the leaf in this machine, and the coolness which is at the same time maintained in the leaf during the rolling process, could scarcely be surpassed, while the machine itself is a combination of strength and cleanliness, with evidently a great economy of power. Mr. Bamber further stated that, after having carefully perused Mr. Davidson's new catalogue, he considers that in the machines now illustrated and described for the first time, and also in the older machines, with the improvements which Mr. Davidson has lately made on some of them, the several chemical and other requirements for the manufacture of good tea are eminently combined.

The four soil workmen. Assuming that all food elements required are present in sufficient supply in a given soil, says an exchange, four important agents must still co-operate before the seed can germinate and the plant partake of the foods provided. These are heat, air, water and light. If there is a deficiency or excess of any one of this quartet, plant life suffers ; if all are present in right proportions, the plant reaches its highest perfection. Each plant has its own requirement of heat, air, and water, but when a fine-texture soil has a temperature of 75 to 90 degrees F., and contains 20 to 30 per cent. of its bulk of water, or 16 to 20 pounds of water to each 100 pounds of soil, and the air can permeate freely, we have the most favourable conditions for the growth of our ordinary field crops. This would mean a temperature about equal to the summer of 1895 in Eastern Kansas, with a supply of water in the soil equal to three inches constantly maintained for every foot in depth of soil. It would also mean a soil in good physical condition, that the air may co-operate with the heat and water.

The Pension Scheme again. Under this heading, our worthy contemporary, *the Indian Planters' Gazette*, notices the revived interest now taken in this subject in Upper India. Until, however, it is thoroughly grasped by the great Calcutta Companies, that the move must come from the employers—and not the employed—any scheme for starting a Provident or Pension Fund for the planting community must fail. Such action may, in truth, partake of grandmotherly nature, and in consequence be resented by the beneficiaries. They may be conciliated by the owners,—be they private planters or companies, paying a proportion of the monthly premia, if only for the first year or so. The main fact to be borne in mind is that the benefits from such a fund will be as much to the good of the proprietors as to that of their employés. Planting life has long suffered under the stigma of being uncertain, happy-go-lucky,—anything, in fact, but stable. This defect removed, as it would partially be by everyone—save private owners—being compelled to subscribe to the Provident Fund, would be to mutual advantage of the whole industry.

A live soil. In an interesting article in the *Central African Times*, Mr. Hizton describes in popular language the function of micro-organisms in the soil :—"When air, water, and heat are in right proportions, the soil is full of life. When the soil is barren, we speak of it as being a 'dead soil,' and when fertile, a 'live soil,' and this is the actual fact. When it is fertile, it is

teeming with life. When there is no activity in the bacteria of the soil, it is barren. The work of these lower organisms is important. German and French investigators have found from 500,000 to 900,000 germs in a gram of soil (less than half a cubic inch). These micro-organisms can only exist where organic matter is present, and will be many or few as organic matter is abundant or scarce. They are dormant when the temperature of the soil is below 39 degrees F. or above 115 degrees F.; dormant when the moisture contents of the soil falls below 8 to 10 per cent., or about one inch in depth of water to one foot in depth of soil; dormant when the soil is fully saturated with water and dormant when air is excluded either by too much water in the soil or by soil compaction. They are most active when the soil is about half saturated; that is from 20 to 30 per cent. of the bulk of the soil, or say 16 to 20 pounds of water to each cubic foot of soil, and when the temperature of the soil is 75 to 90 degrees F., and the air has free access to supply oxygen."

The coffee market.

A further fall of 1*s.* to 1*s.* 6*d.* has taken place in the terminal market, says the *P. M. Review* of 8th ult., caused by the receipts at Rio and Santos being larger than were expected, and a decided reduction in the Brazilian exchange, which is again below 7*d.* Towards the end of this month some reliance may be placed upon estimates of the growing crop, and should they be unfavourable, an advance would undoubtedly take place, as reports from other producing countries mostly point to smaller crops, that in Java being said to be almost a total failure. Since the recommencement of the auctions on Tuesday, there has been a rather better supply, including both new crop Costa Rica and East India. Of the former, one fine mark, though not quite equal to its average quality, sold at extreme prices; the remainder, which was only of medium quality, sold fairly well, but on a much lower basis than the opening sales of last year. The few marks of East India received were more suitable for export than for the home trade, and though the bold sorts sold at full rates, the next sizes were decidedly cheaper. Of other kinds the sales have been unimportant, and quotations are mostly steady.

Thorough firing and packing of tea.

The London correspondent of a contemporary has some interesting notes on the firing and packing of tea, though low firing and "fine malty-burnt flavour" are scarcely compatible with each other:—"Looking over samples in a broker's office the other day, some teas struck me as selling considerably above their value. In reply to my query, the broker said, 'but they have such a good aroma, that fine malty-burnt which you so seldom g now,' which remark led to a discussion on the firi question. He said there was no doubt teas generally we fired at too high a temperature, and, consequently, avoid burning, were not thoroughly done, from whi resulted want of keeping power, and much of the dull f smelling teas met with in the market. I have no dou there is much truth in this, and teas would arrive in mo satisfactory condition, if at least the latter part of the firin as well as the final firing, was done at a much low temperature than is the usual custom. To do this thorough in all cases means a larger consumption of fuel, and many factories would also require more drying machiner but it would, I believe, amply repay the expenditu From this we went on to discuss packing, and he sai An old planter was saying to me the other day, 'I w always careful to solder in my tea hot.' My reply to th was that I was afraid many more were not sufficient careful not to pack or solder their teas before they we nearly cool, as so long as the tea is hot, it continues to gi out moisture, and it should be allowed to come within n many degrees of the atmosphere before it is packed. have not experimented on this myself, but I would advi some of your readers to try the experiment of packing o chest as it comes off the fire at, say, 240°, and another wh the tea has cooled down to about 100°, and opening the some days afterwards to see which tea seemed in t better condition. Since I had this conversation with n broker friend, a dealer has been asking my opinion on t same subject, as he often found some damaged tea on the t of the chest, though the rest of it was in good order, a this he attributed 'to the tea sweating when packed hot.

The tea market.

Indians.—The quantity catalogu for public sale was smaller than usu for the week following Christmas, says the *P. M. Review* 8th ult., being only 40,97 packages. A good dema prevailed, and prices were somewhat higher than in t closing sales of last year. The inquiry is mainly for t medium and lower descriptions, particularly for the form owing to their cheapness and to buyers evidently appreci ing the fact that it will be difficult to follow present pu chases, especially Assam growths, later on. This also mo or less applies to other growths, as the autumnal Teas w soon be coming forward in increasing quantities; indee many of the parcels in the latest sales had this flavou Dooars growths continue to show improved quality, a meet with a fair amount of competition; while the Assa are quite up to the average and have been readily boug as they are, no doubt, the most useful kinds for blendi purposes. On the other hand, Sylhets and Cachars do n show much improvement, a large portion being of po quality, and this will probably continue to be the case f the remainder of the season. Darjeelings are not ve desirable, the bulk of the supply being almost devoid of t flavour sought after in these growths, while the Travancor with few exceptions, are poor in cup. The following a the figures for December, compared with those in the sa month of 1896:—Imports 21,061,000 lbs., and 18,426, lb deliveries 11,389,003, lbs., against 11,584,000 lbs.; wh the stock is 61,673,000 lbs. and 54,144,000 lbs. respective

Ceylons.—This market opened on Tuesday last, wh the sales consisted of over 26,000 packages, and it w

xpected that with this important quantity, and the pro-ıbility of continued large supplies to come forward, prices ould be forced down to a somewhat lower level. This, owever, was not the case, as the market opened firmly, and ıe closing rates of 1897 were well maintained. This result as due, in some measure, to the buying of several of the rger blending houses, as the quality of the teas generally as not otherwise sufficiently attractive to warrant the good l-round bidding that ensued. The following are the figures r the past month, compared with December, 1896 :—The nports amounted to 6,136,000 lbs. against 7,387,000 lbs., nd the deliveries were 7,286,000 lbs. and 6,990,000 lbs. espectively, while the stock stands at 16,629,000 lbs. as ompared with 18,354,000 lbs.

merican tea market difficulties.

The main trouble with India and Ceylon teas in the American market, states a memorandum from the New ork Office of the Indian Tea Association, is that when teas re sold forward on samples, it is most difficult, if not mpossible, to make the goods match the sample.

A firm may order from standard sample a couple of undred chests of tea ; when the shipment comes forward, his is found to be made up of several "breaks" from one arden, or even from distinct gardens. These lines must iffer somewhat under present conditions of manufacture, nd, as a consequence, the buyer has a right, and exercises t, of rejecting those which are least like the sample. ndeed, he may reject the entire shipment. This may be lone in perfect good faith, for he, in turn, may have sold to is constituents on the original samples, but finds the goods re not suitable for his trade either on account of leaf or iquor not having been matched.

In the event of such rejection, a great deal of cross cor-espondence ensues. The tea may have been paid for on etter of credit. The merchant rejecting it has to notify the ocal agent, who, in turn, notifies his principal in Calcutta r Colombo. Bills have then to be drawn on the shipper, nd there is a delay of from two to three months before natters are adjusted. Or the tea may have been shipped and he documents drawn against. The bills have to be accepted by the merchant who ordered the tea, purely as a matter of courtesy, and bills drawn against the shipper.

In the case of the shipment being taken over subject to revelation and an allowance made, the same tedious process nas to be gone through. The merchant buying on mail samples feels he is running risks, as he is not buying on actual samples drawn from the chests as he would do if the tea was on the spot, or were he a buyer in London, Calcutta, or Colombo. The gist of this trouble is that it is apparently impossible to rely upon teas ordered on samples being matched.

This trouble will exist so long as no provision is made for blending teas in the Eastern markets. Until then there is no guarantee that samples will be accurately matched, and the trade is carried on practically upon the local agents' good character and reliance upon his good faith.

In some cases the buyer of a house refuses to buy on samples, and will only go so far as to order teas on approval. Such orders are at the risk of the local agent, and he in turn has to rely upon the Calcutta buyer following his instructions as to selection of tea. In filling the order, the same difficulty occurs in obtaining long lines, and the shipment is composed of several breaks bought at different prices averaging the limit imposed. The buyer here may select the teas which brought the highest price, and the balance on sale in the open market may lose the shipper the entire margin of profit which would have been obtained had the whole line sold at the average expected.

All in this class of business are of opinion that it would be better, in cases where tea cannot be matched absolutely, or where only a portion of an order can be filled to match the standard, that that portion only be shipped, or the order left unexecuted, rather than that buyers here should be subjected to the trouble and annoyance of dealing with teas they do not want and have not ordered.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

LETTERS TO THE EDITOR.

OIL OF LEMON GRASS.

Sir,—In the last issue of *Planting Opinion* I saw "Oil of Lemon Grass" quoted at 8*d.* per oz. Can you give me, or get for me, particulars of manufacture ? Also tell me if there is any *special* lemon grass needed, or is the common stuff what is wanted ?

Any information on the subject will be esteemed

"By Product."

WANTED : A SUBSTITUTE FOR FISH MANURE.

Sir,—Owing to the failure in the supply of fish manure this season, I shall be much obliged if you, or any of your scientific friends, will suggest, through the medium of your valuable paper, what they consider to be the best alternative manure to take the place of the "Fish ?"

Coorg Planter.

[As the most important manurial constituents of fish are nitrogen and phosphoric acid, a very efficient substitute would be a mixture of bones and poonac. The bones would supply the phosphates, and give lime in addition, while the poonac would give all the nitrogen required.—Ed.]

E. LITHOSPERMA SEED.

Sir,—I am sorry to see "Seed's" letter in *P.O.* From his description of the treatment his *E.L.* seed was subjected to, and their subsequent appearance, there is little doubt that he has *cooked* them.

Soaking the seed in cold water for two or three days is all right ; but the same results can be obtained by sowing at once in the nursery and keeping *well-watered*, say, three times a day until the plants are up.

Getting *wet* and *dry* in the nursery, alternately, is, I have found out, most fatal to the seed.

Light shade is advisable, as the plants have a tendency to burn off as they appear above ground.

Arienkow, Shencottah,
25th January 1898.

B. Nelson.

TERRACING vs. DRAINS.

I.

SIR,—I have followed the articles on the above subject appearing in *P.O.* with the keenest interest, owning a good deal of coffee on steep land in an annual rainfall of 100 inches, and being of opinion, from long practical experience, that in course of time "wash" will denude the steeper portions of its best soil, unless something in the terracing line be done. I quite agree with "H.W.P." that no system of drains on steep land can prevent wash, while terracing will. "1 in 2" is quite correct with regard to cost of drains being insignificant when compared with cost of terracing, yet I am of opinion that at an outlay of Rs. 30 to 50 per acre to obtain a permanent safeguard against denudation would annually repay the first outlay, and render a property a great deal more permanent than otherwise. "1 in 2" gives as a great objection to terracing every line the fact that a greater surface of the soil becoming exposed to the desiccating influences of sun and air will have the ill-effect of drying the soil, and in times of drought the plants dying out altogether. He says "this is no theory; it has been proved often and disastrously enough in most districts." With the exception of plants under one year old, I have never known coffee trees die of drought; and although most of the coffee I know is in an annual rainfall of 50 inches and subject to a five months' drought annually, yet, and even with coffee "in the open," a long drought invariably promotes a heavy wintering, resulting in a heavier crop, and I am positive that in this district (Kadur) no ill-effect need be anticipated from desiccation. In support of above, how often do we all see coffee plants growing above the cuttings of our roads with sometimes half the roots bared and exposed, and yet these trees are none the worse, and crop away splendidly. "1 in 2" also says "the coffee plant is a very shallow-rooted shrub," but he must not forget that the tap-roots of full-grown plants reach to a depth of over four feet. "1 in 2's" objection to broader terraces (10 ft. wide) is quite sound; in fact on reading "H.W.P.'s" first letter giving 4 feet wide as the average width of terraces in Peermaad, it at once struck me that the wider plantings of Southern India (generally $5\frac{1}{2}$ ft. or 6 ft.) necessitating wider terraces and consequently deeper cuttings on the upper side, was almost the one objection to his plans being adopted here. On land of a gradient of even 1 in 1 and plants $5\frac{1}{2}$ feet apart, the cuttings below the surface would be $2\frac{3}{4}$ ft. on the upper extreme of the terrace, decreasing to the centre, where the original level of the land would be maintained, the thrown soil from the cutting would be banked up below the plant forming the lower half of the terrace. I cannot see how the argument of insufficient depth of soil holds good in this case, as the plants would be standing in the original soil and only the soil from the upper half of the terrace from high up and above the plant roots will have been removed and placed in a much more readily available position, and it is not difficult to place the top soil near the plants (centre of terrace) and utilize the subsoil and stones for constructing the embankment. A real objection to the above works may be the difficulty in making the terraces hold together without slipping, and on this subject, as also the current rates of terracing in Peermaad, some remarks from a planter who has done this work extensively would be much valued and accepted. I have written the above not to air my views but solely to invite criticism and discussion on a most interesting subject. I am a practical planter, and I regret my pen be not that of a ready writer.

KADUR, MYSORE,
20th January, 1898. NEMO.

II.

SIR,—Your correspondent "1 in 2," who writes on the above subject in your issue of the 15th instant, does not seem to realise what his *nom de plume* means, for he evidently considers that "cutting into hard subsoil to make terraces" would be neces on all ordinary hill plantations, the average slope of whic if anything, less than 1 in 2. But in your issue of the instant, it was shown by me that the cutting required to ma four-foot terrace, on ground having such a slope, woul only that of a triangular "bench," whose base was two feet height one foot, so that the maximum depth of cutting requ would be only a foot, while the average depth would be *inches*. And as "the first foot of soil is ever so much che to dig than the second," the cost of terracing an acre sh not run out to very much.

In regard to this cost "1 in 2" considers the calculat which I gave as extraordinary; apparently because I did quote any money rates, which he thinks I should have ascer ed locally. But all considerations of such money rates purposely avoided by me, and only the actual quantities of calculated, because in the first place, only a comparison betw the two systems was required, and the work (surface digg being the same in each, this comparison was not affected by rates; and secondly, because money rates may, and do, vary each locality, although the quantity of work remains the sa

In the calculations I gave it was assumed that the d would require to be annually cleared of an amount of silt e to their capacity, but "1 in 2" states that "the amount of deposited would be half the depth only." This modifica practically amounts to adding about a year on to the tim which the costs of the two systems would become equal.

For under it in four years time and in 1 in 2 ground the dr would require $3,780+4\times1,890=11,340$ cubic feet of dig work against 10,500 cubic feet for terracing. Similarly in 1 ground the drains in three years time would require $3,360+$ $1,680=8,400$ cubic feet of work against 7,000 cubic feet only terracing.

It should be noted that these are the actual amounts of w or labour required, and if the rates of payment are just, should be proportional to them.

"1 in 2" states that the cost of cutting the six drains woul from Rs. 7 to 10 per acre, and that they could be cleaned out a annual cost of only Rs. 2 per acre. If his second rate (per 1, cubic feet for the earthwork), which appears a very low on correct, he would be paying his men more than double on first! Moreover, applying either of these rates to the quantitie work given above, the ratio between the costs of the two syst would still be the same, and the time in which they become e would be unaltered. Of course if, as "1 in 2" finds terra costs from Rs. 30 to 50 per acre against only Rs. 10 in charge, and Rs. 2 maintenance for drains, it would require years to make the costs of the two systems equal. But ther no reason why terracing should cost so much, for the quant of work required, as shown by me above, become equal in than three or four years according to the slope. Thus tak the lower of the two rates mentioned by "1 in 2," which equivalent to about Re. 1-2 per 1,000 c. ft. of digging work, cost of terracing in 1 in 2 soil would be only Rs. 11-13 acre, and in 1 in 3 soil it would be less than Rs. 8 per acre. rate, however, as stated before, is a very low one, and the cost would probably be about double these amounts.

A great objection that "1 in 2" sees in terracing is that it poses an increased surface of soil to desiccating influences of and air; and he suggests either to have wider terraces with rows of plants on each, or else a series of one-foot deep trenc between every two rows of plants.

This objection, however, is limited by him to coffee est only, and appears to be due to his misconception of the de of cutting required for terracing, which he evidently regard considerable. But, as shown above, the maximum depth cutting for terracing in 1 in 2 ground is only 12 inches, the average depth is 6 inches, or *half* that which would

equired for his trenches at the same time, while the terrace ould expose only one cut face to the sun and air for each row f plants, the trenches would expose two. The proposal to ncrease the width of each terrace and put a double row of lants on it, would neither remove nor reduce the exposure of ne outer row of plants, while the increased width would very onsiderably increase the depth and cost of cutting the terraces. o also the suggestion to build low retaining walls where the eld to be terraced was "exceptionally rocky,"—if such a field ould ever be cultivated and need terracing,—would add normously to the cost of the work. Lastly, but not leastly, n the trench system the slope of the ground surface would emain unaltered, instead of being reduced to almost zero in the errace, and the denudation of the surface soil, as explained in ny first letter, would go on the same as before, not only mpoverishing the soil, but also silting up the trenches of which here would be no less than thirty-six to dig and maintain n every acre, against six in the ordinary system and *none* in he terraced one.

PEERMAAD,
27th January 1898. } H. W. P.

DISTRICT ASSOCIATIONS.

CENTRAL TRAVANCORE.

A Committee Meeting of this Association was held at Penshurst Bungalow on January 22nd at 10 A.M., when there were present:—Messrs. F. M. Parker (*Chairman*), H. W. Baker, R. H. Goldie, R. S. Imray, B. Laurie, and A. E. Veale. Dr. Joseph also attended by special request.

Medical Fund.—The Honorary Secretary informed the meeting that H. H. Government had sanctioned two medical grants-in-aid of Rs.100 each per mensem to the Bon Ami and Carady Goody Dispensaries, the former from 15th February 1896 and the latter from 22nd December 1897.

Recorded with satisfaction.

The Honorary Secretary was instructed to indent for instruments as required by Government Regulations as speedily as possible.

Plans of proposed new Doctor's bungalow, Medical Store, and Consulting Room and Dispensaries having been submitted and approved, the Honorary Secretary was instructed to call for tenders for their erection.

The following rules were then framed and adopted:—

(2) That the Doctor and Apothecaries be each required to keep a diary.

(1) That every employé of the fund be allowed one month's leave per annum on full pay.

Read Doctor's applications for horse allowance and leave.

Resolved: "That the Doctor be allowed Rs. 25 per mensem for horse-keep."

"That the Doctor be permitted to take one month's leave from 10th February."

With a vote of thanks to the chair the meeting terminated.

A. E. VEALE,
Honorary Secretary,
January 25th, 1898. *C. T. P. Assn., Medical Fund.*

WYNAAD.

PROCEEDINGS of the Annual General Meeting held at Meppadi Club on January 5th, 1898. *Present*:—Messrs. Abbot, Behr, Day, DeFonblanque, D. Mackenzie, W. R. Mackenzie, Mackinlay, B. Malcolm, J. R. Malcolm, Robinson, Romilly, Tayler, Trollope, Waddington, R. K. Walker, West, Wright, and Hockin, *Honorary Secretary*. Mr. G. Romilly, *in the chair*.

ANNUAL REPORT FOR 1897.

The Hon. Secretary read the following report for the past year:—MR CHAIRMAN AND GENTLEMEN,—In this report I propose to follow the lines of the last annual report, adding fresh matters in the proper place.

1. *South India Planters' Enquiry Committee.*—The report of the Committee reached us early in June, and the Government of Madras were good enough to give us time till after the Annual U. P. A. S. I. Meeting in August to discuss it. Although the Committee did not approve of all the reforms planters asked for, yet the chief findings are so much in accord with the planters' case, that our 30 years' agitation about the Labour Law is fully justified. Whatever may become of the actual recommendations of the Committee, we have in the report a record and vindication of our cause, which will strengthen our hands enormously in any action which it may be necessary to take in the future. As such, the report was cordially approved of by this Association and the U. P. A. S. I., and the recommendations accepted with the exception of two or three points of minor importance. 2. The Proceedings of the last annual meeting were fully reported in the papers, and the report of the delegates of this Association printed in our September Proceedings, so that I need only refer briefly to the chief results of the meeting. The finances of the Association were reorganised and established on a basis which, it is hoped, will give the U. P. A. S. I. a steady income of about Rs.5,000 a year. This basis is a vote for every Rs.10 subscribed by each District Association, such subscription not to exceed 1 a. or fall below ¼ a. per cultivated acre in each district, and the votes to be held by the delegates of the Association. The scheme of individual membership was generally disapproved and withdrawn. A Reserve Fund of Rs.8,825-12-0 was established, of which Rs.5,000 has been placed at deposit with Messrs. Arbuthnot & Co., and the rest kept in hand to meet payments voted, if certain conditions are fulfilled. One of these payments is Rs.2,000 towards the introduction of lady-birds to combat scale pests, and I think this payment will have to be made, as the Govt. of Madras have agreed to pay half the cost, and the Lower Pulneys are also prepared to pay up handsomely. Another payment was Rs.2,000 per annum towards the expense of an Agricultural Chemist, if District Associations and the various Governments concerned will also contribute. I think it doubtful if this payment will be made, as I am informed the Mysore Govt. will engage a chemist and collect subscriptions for Mysore planters, and that the only other district which will contribute any considerable sum is the Nilgiris, which promises Rs.2,100 per annum. The Shevaroys may also subscribe, but two districts will hardly provide enough money to start such an expensive scheme. The third payment is Rs.1,000 towards the expenses of Mr. Cameron, if the Mysore Govt. will lend his services for the improvement of the strain of coffee. I do not know if this payment will be required or

not. The other important resolutions passed were in favour of reopening the mints; of an export tax on bones; of the registration of the U. P. A. S. I. as a public company; of paying counsel's fees and legal expenses in connection with the case referred to the High Court *re* warrants under Act XIII. of 1859; of the investigation of the malarial parasite when Govt. funds allow of it; and of the U. P. A. S. I. backing up all complaints from District Associations about important roads. The Govt. of Madras has strongly recommended to the Govt. of India the U. P. A. S. I. resolution of 1896 in favour of the exemption of chemical manures from import duty, and has authorised the Director of Govt. Cinchona Gardens to purchase from planters in India any bark which may be required to supplement the supply from the Govt. Gardens. The rules of the Association were amended to meet the new scheme of voting and finance, and a portion of *Planting Opinion* is to be devoted to U. P. A. S. I. matters under the control of the Secretary. As I was unable to get any adequate return of Wynaad statistics, I asked the Secretary to take those given in *Planting Opinion* and these are published in the appendix to the report of 1897. I would ask members to refer to this, and correct any mistakes they find through the Hon. Secretary.

Roads.—As usual this subject has received considerable attention from the Association. It has come up at every meeting this year, and a special meeting was called in May for the Vayitri-Calicut road. Before this meeting, however, I had asked Mr. Romilly to interview His Excellency the Governor on the subject, and was able to assure the meeting that His Excellency hoped to have a special grant made at an early date. The District Board had estimated that a grant of Rs.26,000 from Provincial Funds would be required to enable it to put the road in proper order. At the end of August I received a telegram to the effect that a grant of Rs.20,000 had been made. The remaining Rs.6,000 is the usual annual Provincial Fund grant which for some unknown reason was omitted. Of the Rs.20,000 sanctioned, Rs.14,000 was for the Talipoya bridge, and I see from the District Board Proceedings of the 9th October, that Rs.10,000 is to be spent this year and Rs.4,000 held over till next year. Of the other Rs.6,000, Rs.6,700 was sanctioned on the same date for special repairs to deep tracts on the Tamaracherry ghat and the remainder was spent on the section of the Vayitri-Calicut roads below the ghat. Our request for the deputation of an independent officer to report on the system of roads in Wynaad was refused; but we have an excellent advocate of our cause in the President of the District Board, to whom our best thanks are due. In August last I addressed the Secretary to the Dewan of Mysore on the condition of the Mysore section of the Sultan's Battery and Mysore road, and receiving no answer, sent him a reminder. Lately I received a request that I would furnish him with a copy of my letter, which had apparently miscarried, and forwarded the copy asked for.

Act XIII. of 1899.—A form of contract under this Act has been drawn up by Messrs. Winterton and Edge, and twice revised. Copies of the new form have been sent to all members of the Association. On a reference being made to the High Court by order of the Government of India, it has been decided that warrants under the Act can be legally executed outside the jurisdiction of the issuing magistrate, as has been the custom for the last 38 years.

Famine Fund.—Rs.1,195 have been collected from members of the Association and forwarded to the Secretary, U. P. A. S. I.

Treasury.—We have twice had to complain of the absence of small change, and once of the absence for nine days, of any money at all to cash money orders in the Vayitri Sub-Treasury. The replies from the Postmaster-General amount to a statement that an enquiry will be made, but I have not heard the result of these enquiries. I have, as requested, addressed the Hon'ble Mr. H. P. Hodgson, and asked him to make an interpellation in Council as to whether the Postal Department is not bound to cash all money orders on presentation. The replies from the Collector of Malabar state that the want of small change, or cash generally, is due to the difficulty of getting police for escort duty, and that the Inspector-General of police has been asked to supply more police for Malabar. As the Post Office makes an income of Rs.400 to Rs.500 a month from money order commissions in Wynaad, it does not seem asking much that it should retain enough police in its pay to secure an escort for money when necessary. The granting of drafts on local Treasuries has been refused, although we have addressed both the Governm of Madras and India on the subject. I understand that a si concession in Coorg is only granted because Government has m there it cannot employ otherwise.

Medical Fund.—This has been reorganised and subscription now raised on an acreage assessment. As a consequence we provide a doctor and four apothecaries, where we formerly supp only a doctor and one apothecary.

Miscellaneous.—The Association approved of the agitation for reopening of the mints, but disapproved of the schemes for disease remedies and the employment of an agricultural chem and has not subscribed to the introduction of lady-birds to con scale pests. A register of planters who pay tax direct to Gov ment has been opened in the Wynaad Tahsildar's Office, so that lands may not be sold for default of our jenmies A complaint to non-service of warrants in Coimbatore has been met by the is of a circular by the Superintendent of Police to all Inspect warning them that neglect of duty under this head will be seve punished. I believe one Inspector has been suspended and fi but I have not yet caught a man one of my maistries has b hunting for months back. The Association has agreed to pa monthly subscription towards the Pudupadi Hotel, but it is easy to see where the money is to come from unless subscripti are raised. Finally, it has been resolved to appoint a Chairman Committee yearly to conduct the business of the Association.

General Remarks.—We have lost one member by death and two h resigned. Three new members have been elected, so that the num of members still stands at 40. Tea continues to be extended, will shortly require an increased supply of labour, which it sho not be difficult to get. Arabica crops are very short this year, a the case in most parts of Southern India. Prospects for next y are, however, very good, there being every indication of a plent show of spike. Liberian coffee continues much as last year, an not likely to be extended largely until good crops are realised. of the greatest dangers to the future prosperity of the district in the action of Government in forcing up exchange, while our c petitors in both tea and coffee enjoy an unprecedentedly low rat exchange. With Brazil exchange at the equivalent of 7*d.* per ru and consequently Brazil coffee in superabundance @ 25*s.* to 30 cwt., we may consider ourselves lucky that our prices for Arab coffee have fallen only from 100*s.* to 80*s.*, although Liberian gone down from 75*s.* to 45*s.* Any further fall in price, coupled w high exchange, would render the cultivation of Arabica unprofita It is difficult to regard with equanimity the adherence of Gov ment to a policy which threatens to ruin our industry and whole export trade of India. Another very great danger to prosperity is the insufficient grant for the upkeep of roads. E of the small allotments made this year, that for the Chundale-Mys frontier road has been reduced, and the President of the Dist Board informs me it will be necessary to again reduce the grant Wynaad roads very largely in 1899, in order to allow of repairs other important roads in Malabar. The effect of the reduction year has been a serious deterioration in the roads, and consequen of higher prices for all food supplies than should have ruled e in this year of famine. These high prices if continued will hav most disastrous effect on our labour supply, just as it has bec necessary to increase it largely. We should leave no stone untur to endeavour to obtain from Provincial Funds grants for our ro similar to those given in Nilgiri-Wynaad for the sections of roads which lie in that district. The weather has not been so ba last year, but this year's rainfall is the third heaviest rainfall record in twenty years, and last year's was the heaviest. That of year before was well above normal, and we must hope that a three years of abnormal rain, we may have a return to lighter more normal monsoons. I lay the accounts on the table, and will see from them that it will be necessary to consider how fu are to be found to meet the present expenditure. It only remains me to lay my resignation in your hands, and to say I shall be glad if some other gentleman will consent to be Honorary Secret as I find I have not time to attend to the business properly. work is much more than it used to be, and promises to be hea still in the future. Whoever takes the post should, I think relieved of part of the work. If this can be arranged by

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

Chairman and Committee, each of them taking charge of one or two branches, I am sure no one will welcome the appointment of the Committee more than the Honorary Secretary will.

J. WILLIAMS HOCKIN,
Honorary Secretary, W. P. A.

Proposed by the Chairman, seconded by Mr. R. K. Walker, that the report be adopted. Carried unanimously.

2. *Finance.*—The accounts for 1897 were circulated and passed; Rs.100 were subscribed in the room to meet the deficit shown therein.

3. *Vote of thanks to the Hon. Secretary.*—The Chairman proposed a cordial vote of thanks to Mr. Hockin for his services during the four years in which he had held office. Mr. Hockin had been a most excellent Hon. Secretary, and had done a great deal of important work for them, especially with regard to the Revenue Settlement, and he (the Chairman) was very sorry he was not offering himself for re-election. Seconded by Mr. R. K. Walker, and carried unanimously. Mr. Hockin, in returning thanks, said that he only resigned because he had not time to attend to the regular routine of work properly, but he was quite prepared to do a certain share of work in the future.

4. *Election of office-bearers.*—Proposed by Mr. Hockin, seconded by Mr. deFonblanque, that Mr. R. K. Walker be elected Chairman for the coming year. Carried unanimously. Proposed by Mr. Wright, seconded by Mr. B. Malcolm, that Mr. deFonblanque be elected Honorary Secretary. Carried unanimously. A ballot for the Committee was then held, and the following gentlemen declared elected:—

For Vayitri—Messrs. J. W. Hockin and R. Lamb.
„ Meppadi „ W. Hockin and Romilly.
„ Vellera Mulla—Mr. B. Malcolm.

A vote of thanks to Mr. Romilly for his services as Chairman was passed, and the meeting then resolved into the Monthly General Meeting.

(Signed) G. ROMILLY, *Chairman.*
(„) J. WILLIAMS HOCKIN, *Hon. Secretary.*

GENERAL MONTHLY MEETING.

Mr. R. K. WALKER in the chair.
Mr. DEFONBLANQUE, *Honorary Secretary.*

1. Proceedings of last meeting were taken as read.

2. *Amendment of Rules.*—Resolved that the Committee be requested to revise the rules and submit any amendments they consider necessary for the approval of the general meeting.

3. *Cattle Trespass Act Amendment.*—Read letter from Mr. Powell to the Honorary Secretary complaining that the fines for cattle trespass had not been enhanced in Wynaad as the Association supposed they had. Also letter from the Honorary Secretary to the Collector of Malabar asking that such enhancement of fines might be proclaimed in Wynaad as had been done in the Nilgiri District. Approved.

4. *Roads.*—Read letter from Honorary Secretary to President, District Board, dated December 2nd, 1897. Approved.

The Chairman proposed that the Hon. Secretary be requested to address the Chairman, U. P. A. S. I., asking him to approach Government on the transfer of the Calicut-Ootacamnnd road to the Department of Public Works. Carried unanimously.

The Honorary Secretary was requested to ask the President, Malabar District Board, for copies of road allotments for 1898-99, Wynaad and Calicut Taluqs.

Mr. Hockin resigned his place as Member of the District Board, and Mr. R. K. Walker agreed to allow himself to be nominated for the post.

5. *Revenue Settlement.*—Read letter from Collector of Malabar to Honorary Secretary. Resolved that the following paras. be printed for the information of members:—

Para. 3. If European planters holding lands under native jenmies are willing to send lists of them to the Taluk Office, I will direct the Tahsildar to enter them in a register to be opened for the purpose.

Para. 4. The lists should contain the following particulars:—Survey No. and desam. Extent in acres. Assessment. Name of land. Name of janmi. Name of holder or occupant.

The Honorary Secretary was requested to thank the Collector of Malabar for his acceptance of the Association's suggestion, and to inform him that his orders were being circulated for the information of members.

6. *Poodoopadi Hotel.*—Read Honorary Secretary's letter to the proprietor and letter from Mr. T. J. Ferguson to the Honorary Secretary. The Committee were requested to look into the matter and arrange matters on a proper footing.

7. *General Meetings.*—Resolved that the General Meetings in 1898 be held on the first Wednesdays in the following months: January, February, March, July, September, October, November, December; or 8 in all, unless the Committee think any Extraordinary General Meetings necessary.

8. *U. P. A. S. I. Circulars re* Agricultural Chemist, greenbug and lady-birds, and Mr. Quarme's scheme. Recorded.

9. *Papers on Table.*—Nilgiri Planters' Association Proceedings, 26th November 1897; Government of India Commercial Circulars, No. 11 of 1897, on Bamboos.

(Signed) R. K. WALKER, *Chairman.*
(„) E. DEFONBLANQUE, *Honorary Secretary.*

THE LIGHT THAT CAST NO SHADOW.

CURIOUS stories are told about the powers possessed by certain natives of India, who live up among the Himalaya mountains. These old men, it is said, have devoted scores of years to the study of natural laws and forces, which the rest of the world knows nothing about. Lately a German professor visited the "adepts," as these queer Hindus are called, for the purpose of finding out the secret of their remarkable performances. They treated him rather scurvily, but interested him all the same. One day the professor wanted to examine some ancient Sanskrit manuscripts. An adept went with him to a cave wherein the books were kept. The place was dark as the bottom of a well.

"I can't see to read here," said the visitor.

"Then we will have some light," was the reply, and immediately (the professor says) a soft, pearly light brightened the cave. He could not tell whence it came, but he noticed that it had one strange quality—*it cast not the slightest shadow.*

This is a story hard to believe, yet its truth is affirmed by a man of vast learning and high character, and you who now read it have no reason for doubt except that all the lights *you* have seen have cast shadows. Belief or unbelief commonly runs parallel with one's own experience. Dr. Johnson sniffed at the account of the Lisbon earthquake, yet credited the tale of the Cock Lane ghost.

A man who has been ill for years, and failed to find a cure, is sceptical when friends tell him of a medicine which they believe will make him well. What else but doubt could result from his experience? Take an example:—

"In the spring of 1888," writes our correspondent, "I fell into a low, weak, and languid state. I felt low-spirited and out of sorts. At first my stomach was deranged, my appetite poor, and after eating I had pain and weight at the chest. I was much troubled with wind, and frequently spat up a sour fluid, also bitter bile. Later on I suffered from nervousness and great depression of spirits. I kept up with my work, but had always a sense of discomfort. Off and on I continued in this way for two years, nothing that I took relieving me. At last I heard of Mother Seigel's Syrup, and procured a supply. After I had taken only a few doses I found relief; my food digested, and gradually all nervousness left me. Although I had no reason at first to feel any confidence in this medicine, never having used it or seen it used, I now gladly admit its value, and its power over disease. Since my recovery, for which I thank Mother Seigel's Curative Syrup, I have been in the best of health and spirits. In the interests of suffering humanity, I deem it a duty to send you this testimony. (Signed) D. Griffiths, tailor and outfitter, 151, Hockley Hill, Birmingham, June 8th, 1893."

There is a deal of difference between Mr. Griffiths' candid letter and the story about the light that cast no shadow. The latter may be true enough, but it cannot be verified without more trouble than it is worth. On the other hand we have a trustworthy witness, who will answer letters of inquiry, and can be found at his address.

Finally, there is nothing mystic or magical about Mother Seigel's Curative Syrup. It acts on the theory that most ailments are but symptoms, forms, or phases of that universal disease—indigestion and dyspepsia; it cures that, and throws the light of health and happiness over hearths and homes where illness and pain had cast such dark and terrifying shadows. And that is why people believe all that is told of its success by eager witnesses.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (January 14, 1898) says:—A quiet tone has prevailed at Public sale this week and the moderate supplies brought forward met a slow demand at barely steady prices.

Nearly 1,300 bags East India were offered and attracted fair competition at about previous values whilst here and there a fine colory lot realised extreme rates.

Columbian, which formed the bulk of the Central American offered, was difficult to dispose of and a large proportion had to be bought in, the rest setting at unchanged to rather easier prices.

Futures after declining 1/- to 1/6 during the first half of the week on larger Brazilian receipts, recovered the last day or two and the market closes about 6d. lower than our last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending January 12th, 1898, says:—Bank rate 3%. Bombay Exchange closes at 1s. 4 1/16d. Brazil Exchange 6 15/16d. Rupee paper 3½ % 62⅝. Silver 26 9/16d. per oz.

This market has been dull throughout the past week, and closes easier, except for fine and good middling. The better kinds of new crop East India met with a good demand, whilst the pale and grey sorts are difficult of sale, and chiefly bought in. Brazil markets are flat.

According to Messrs. G. Duuring and Zoon, the European stocks on 1st inst. shewed an increase of about 12,050 tons, and the visible supply a decrease of about 4,870 tons, the figures being 170,150 tons and 370,000 tons respectively, against 158,100 tons and 374,870 tons on the 1st December, 1897.

Daily receipts averaged 8,000 bags in Rio and 14,800 bags in Santos.

Futures continue dull and declining, prices at the close being 1s. 3d. to 1s. 9d. per cwt. lower, viz.:—Good average Santos in Havre, March delivery, fcs. 37·50, in Hamburg pf. 30¾, and No. 7 low ordinary Rio in New York $5.65.

Stocks of all Tea in U. K. on 31st December, 1897, lbs. 101,869,604; 1896, 103,798,893; 1895, 101,335,543.

Indian. Monday's sale of 43,988 pkgs. was the largest Indian Tea auction ever held in one day in London. The market stood the strain very well and passed without quotable alteration, although here and there, as was to be expected, a few lots sold rather easily, especially amongst medium brokens.

Week's av. of Tea sold on Garden Account, 1898, 44,253 pkgs., av. 8·39d. 1897, 40,471 pkgs., av. 9d.

Java. Only 302 pkgs. were brought forward consisting of Teas of direct import the sale passing without material change. 108 pkgs. "Perbawattee," av. 11d. per lb. 108 pkgs. "Goalpara," av. 9¼d. per lb.

OTHER PRODUCTS.

CAMPHOR (CRUDE).—Quotations of *Japan* by cable have advanced to 95*s.* per cwt., c.i.f. terms for February-March shipment being asked. This is an advance of about 4*s.* per cwt. London holders want 2*s.* more.

CANNABIS INDICA has been advanced from 4*d.* to 5*d.* per lb. for good green on stalk. The stock in London is low (some forty-five or fifty bags), and the advance has been made on advices from India, where the stock is also moderate; but the real reason for the advance is that the Indian holders want more money.

CINCHONA.—The future of the bark is still dubious, but the general feeling is that the Java output will be less this year, and that next week's bark-sales will stiffen prices.

IPECACUANHA is unchanged, but firmly held at our previous quotations.

JALAP.—There is no business to report at the nominal quotation of 6½*d.* per lb.

KOLA NUTS.—At the spice auctions two packages of fair to dark West Indian sold at from 4*d.* to 5*d.* per lb.

QUININE.—There is no visible change to report, although small sales of B. & S. at 1*s.* 1*d.* per oz. have been made by the makers. No more is to be sold at that price. Samples of quinine sulphate manufactured in Java have been received in London. It appears to be a good article, but not quite white, the colour being between that of unbleached sulphate and the B.P. article.

SPICES.—Public sales were resumed on Wednesday, after an interval of four weeks. There was little disposition to do business on the part of the buyers. Cochin *Ginger* was especially dull, only a small proportion selling; 80 bags good plump washed rough realised 24*s.* to 24*s.* 6*d.* per cwt.; 354 bags common small wormy rough, 15*s.* per cwt.; 20 bags dusty cuttings, 12*s.* per cwt.; and 43 cases medium and bold native cut, limed, and slightly wormy 38*s.* 6*d.* to 40*s.* per cwt. Of Jamaican only a few barrels sold at 70*s.* to 72*s.* per cwt. for ordinary lean. Japan ginger was bought in at 14*s.* 6*d.* per cwt.

ZANZIBAR *Cloves* are dearer; 170 bales sold at 3*d.* per lb. for dull, at 3⅛*d.* for fair to good fair; while good realised 3¼*d.* per lb. Privately there has been a good demand on the spot at prices rising from 3*d.* to 3⅛*d.* on the basis of fair. The demand for future delivery has continued, and 3⅛*d.* has been paid for January-March, 3¼*d.* for March-May, and 3 9/32*d.* for April-June. *Nutmegs* and *Mace* are unchanged, and only partly sold at about steady rates.

BLACK *Pepper* steady at 3⅞*d.* per lb. for Singapore on the spot. For arrival 4 1/16*d.* has been paid for January-March shipment. Penang and Lampong were bought in, and 20 bags fine bright heavy Wynaad sold at 4*d.* per lb. Penang was bought in at 6*d.* per lb., and Siam at 7*d.* per lb. For arrival, Singapore has sold at 7¼*d.* to 7 5/16*d.*, and Penang at 6 1/16*d.* to 6¼*d.* per lb., according to position, being rather dearer. *Cinnamon* chips partly sold at 2¾*d.* per lb. for ordinary small dusty.

THE PLANTER

Is a WEEKLY JOURNAL conducted under supervision practically skilled in planting matters. It contains leading articles by experts, short mofussil notes and letters from correspondents in the various planting districts, after-edits upon topics of general interest to estates managers and assistants, Calcutta Notes, Companies' Reports, Commercial Notes, Indigo, Coffee, Jute, and Tea Market Reports, Home News, Tea Sales and comparative tables showing the position and returns of Calcutta and London Tea Companies.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, ght Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including ostage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for ne advertisements will be: 4 as. per line for the first, 3 as. for the second, nd 2 as. for the third and succeeding insertions. Five-line advertisements om Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic ccurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," splanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been emoved to Madras, all remittances should be made payble to the Manager of *Planting Opinion*, 3, Esplanade ow, Madras, who will also attend to all advertisements, &c. Letters to the Editor should be addressed to Coonoor, s usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 18th February, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nilgiris. COONOOR, *9th February.—Weather.*—Clear since last report and still cold, but weather changed yesterday, and to-night it has begun raining smartly, with some thunder. *Crops.*—Coffee not all in yet on high elevation totes, but this rain should hasten them. Prospects generally first-rate for this year. Early blossom thought most probable. *Plant-diseases.*—In abeyance. *General Health.*—Fair. *Labour.*—Ample.

Nellampatty (British). *9th February.—Weather.*—Hot weather has set in, but the last two or three mornings looked very like rain. It is to be hoped none will fall, however, as it would probably mean another bad year, while at present the prospects for next year's crops are decidedly good. Outturns have been rather better this year, and some people attribute this to the new seamless bags being used. *General Health.*—Fair: a little fever among Europeans, but nothing very serious yet. *Labour.*—A number of places have paid off, and more do so this week.

Coorg. POLLI BETTA, *7th February.—Weather.*—After a long absence clouds put in an appearance yesterday, and to-day they gathered in force, and during one part of the day the sky was almost entirely obscured and it looked ominously threatening. Rain now, of course, is very much to be deprecated. *Crops.*—Stripping not all completed yet. Gleaning in progress. Prospects for coming season most encouraging. Old wood bursting with spike. Trees mean to crop if only given a fair chance. Pruning being pushed on with. *General Health.*—Much improved. *Interesting Item.*—Silver cup, value Rs.50, presented by Captain Lambert to "B" Company for best shot at annual course up to 600 yards.

THE MANURING OF ESTATES.

IN the present rudimentary state of planting science, we can conceive nothing that would benefit the industry more in return for the cost than a small travelling committee to collect trustworthy evidence on the comparative results of the different systems of manuring in vogue. Two or three men of known ability and integrity would suffice, and in the course of three months or so they would probably have had time to visit most of the planting districts of South India. It may be said that by issuing circulars, we could ourselves obtain the information desired. We could get it in part, it is true, but the most important half of the information, *i.e.*, the actual results obtained, would be sadly lacking both in quantity and quality. There are very few proprietors or managers who care to furnish details of yield in answer to a journalistic enquiry. Moreover, in the course of conversation, they would be a great deal more likely to supply interesting and valuable details of information than were they required to put it all down on paper.

But we anticipate. Before debating the advisability of a travelling committee in preference to circulars, we should have demonstrated the necessity of holding such an enquiry at all.

Lovers of ancient routine will object to the scheme altogether: for they say with sublime confidence that every man knows the methods of manuring that best suit his estate. Luckily for the prosperity of the community, each year sees the number of these worthy men decrease. We shall not lose time in attempting to convince them, for it would be a waste of space. No discourtesy is meant hereby, for it is a physiological fact that the human mind is incapable of receiving fresh impressions after a certain period. There are, however, another section of objectors. These maintain that it is no good travelling outside your own district, and that in it any man can easily obtain the comparative information he needs. Both of these objections we must negative. The differences in soil and climate between the various planting districts are not so great as to render experience gained, say in Coorg, useless when applied to a Nilgiri or Travancore estate. As a matter of fact, for the purposes of planting they should all be regarded as one district, though bearing in mind their differences sufficiently. The second objection seems a sound one, if one forgets how very little distant neighbours see of each other, though in the same district. Moreover, such inspection, while of undoubted utility, would not be nearly so complete as that instituted by the proposed committee.

To point our remarks, we will cite two cases known to us. Two of the crack estates of a certain district, separated from each other only by a few miles, have gradually differed in their working until the principles adopted are almost contradictory. One estate, after long and careful trials, has come to the conclusion that nothing can beat good cattle-manure. Good cattle-manure not being obtainable by purchase, and grazing being out of the question, the estate cattle are wholly stall-fed, guinea-grass and oil-cakes being their principal food. The other estate has on the contrary, after at least as careful trials, entirely given up the use of cattle-manure, and relies altogether on the aid of artificials and chemicals.

The work of our committee in these two cases would not err on the side of simplicity. Exposure, quality of the soil and subsoil, rainfall, cost of working on both the estat and, lastly, crops for a series of years, should be carefu compared. It is by no means necessary that every est in each district should be visited ; some half-dozen, or doz representative ones would suffice for the purpose.

After all, leaf-disease or no leaf-disease, *the* great questi is to ascertain the results of varying treatment in cro We make bold to say that on the best estates through South India will be found lines of resemblance in the s and methods of manuring and cultivation that will give clue to the great latter-day puzzle : how to get crops, a how to go on getting them.

The first step in organising a science is to coll sufficient data, then to arrange them in succinct order. T next is to deduce therefrom general laws governing facts observed, which laws are again tested by the light actual experience. Planting data are available in gr number : they require collecting and arrangement. Su a task can only be satisfactorily accomplished by mea similiar to the one we have proposed, *i.e.*, by forming small working committee to travel round and inspect chief estates of Southern India.

NOTES.

American Tea Market Fund. The contributions promised this fund amount to Rs.1,02,0 being Rs.1,635 below last yea levy, but this does not include the sum of £200 cont buted by the Assam Company in London.

The Belgian tea duty. The abolition of the duty on in Belgium will tend to an increa continental consumption of this article. The geographi position of the country is admirably suited to the establi ment therein of large *entrepôts*, from which the neighbo ing estates can be easily and quickly supplied.

India-rubber in Australia. Australia is beginning to wake to the possibilities of its sub-tropi and tropical zones. Coffee is obta ing a firm footing in Queensland, and now systematic effo are being made to introduce rubber cultivation in Northern Territory of South Australia. Arrangements being made by the local Government for the planting half a million acres.

Tea: bulking of same marks. The following regulations, affo ing further facilities for the bu ing of Indian and Ceylon tea, to be brought into effect in the port of London on representation of the Indian Tea Association.

"(1) Parcels of Indian and Ceylon tea bearing the sa garden mark, but imported by different ships, may bulked together for home consumption, exportation or shi stores.

"(2) On request to the surveyor at the station at wh any tea proposed to be dealt with under this order is to warehoused, the bringing to account of the first and sub quent consignments may be deferred until all the packa have arrived, provided that no packages remain in wa house for more than two months, from the date of the shi report, without being weighed and brought into accou

The Papaiya for planters.

Says our pushing contemporary, the *Produce World* :—" A source of income to which we would draw the ttention of planters is Papia juice. The Papia (otherwise 'apaw) tree is of quick growth, and thrives wonderfully hroughout the tropics. It needs practically no cultivation, nd its richness in pepsine is too well known to need re-apitulation. The pepsine derived from this fruit is the oundation of most medicines for curing digestive derange-ients, and is now quoted at 5*s.* per lb. It is easily prepared, nd we should advise its inclusion amongst shade trees on ll estates where coolie labour is used. The unripe fruit as to be scarred or lined some quarter inch deep, with a harp knife daily, and the juice caught and dried upon heets of glass, when it becomes at once a marketable ommodity. The *Chemist and Druggist* gives the following ethod of preparing it :—'The juice is pressed out of the ruit, clarified by filtration through a twill bag, and the erment precipitated by alcohol. It is then dried, but is ometimes purified by treatment with water.'"

Camphor shade.

As a matter of fact, we do not think that camphor would do extra vell for shade, though if used in belts for protection against old winds, its somewhat dense foliage would be of value. t should be tried though, at least, for from its leaves that ost valuable of all products, camphor, can be distilled from he fourth year. We believe plants can be obtained from he Curator of the Ooty Botanical Gardens. Its culture is eing tried in Florida with encouraging results. At present ve are dependent upon Japan and the Phillippines for amphor, and since the rebellion in the latter islands, the rug has gone up considerably. In Japan camphor is one f the noblest trees of the forest, and its timber fetches a ood price for various purposes. At any rate whoever vishes to undertake the cultivation of camphor had better egin soon, for the number of places where the tree thrives s legion. Egypt, the Canaries, South-East France, Buenos yres, California and Madagascar are all countries where amphor thrives. In Japan the trees withstand the frosty ights of winter, and a minimum temperature of 12° F. n Australia, too, camphor grows very freely. The increased emand for camphor for use in explosives and in the manu-acture of celluloid gives greater importance than ever to his commodity. The Japanese have commenced to prepare t by distilling the leaves and branches of the trees instead f destroying only full-grown trees for the purpose.

The value of forest fires.

According to Dr. Bell, in the *Scottish Geographical Magazine*, the orest fires of Canada are generally caused by lightning. n the great forest between Alaska and the Straits of Bellisle, the portions recently burned are easily recognised y the tenderer green of their foliage from the parts which ave been longer spared. The fire rushes along with the peed of a galloping horse. The branches and dead leaves n the ground burn like tinder, and the flames rise to near-y 200 feet. Resinous pine-woods burn fastest. One of them xtended 160 miles in ten hours. The traces of a fire emain for nearly a century. Birds and beasts are stifled or urned. Beavers and muskrats, which are amphibious, ave a chance of saving their lives.

After the fire a few trunks of the largest trees are left. Next spring roots begin to sprout, and seeds to grow. In 15 or 20 years the soil is covered with poplars, willows, &c., which shelter young firs and other trees. In 50 years the conifers are uppermost, and in 100 the others are dying out beneath the pinewood. A third of the forest region of Alaska has trees of 50 years' old, another third trees of 50 to 100 years, and the rest trees over 100 years' old. The fire seems to suit the Banksian pine, as it opens the pines and sets free the grains. Without fires this species would hardly reproduce itself. Such fires took place even in the Pleistocene epoch of geology.

Forests and rainfall.

It is well established that forests tend to preserve the rainfall of a district. They permit what Americans call a "seepage" of water to the source of springs, and also retain the snow or rain that falls, thus preventing dangerous floods and freshes. It is not settled, however, whether they tend to promote snow or rainfall. There are plenty of historical statements which might be taken to show that they do; but the evidence is doubtful. Dense forests are usually found with abundant rains, but the rains there probably caused the forests. Meteorologists are agreed that no important changes of climate have occurred since the dawn of history. Plants found in mummy cases in Egypt are such as grow in the land to-day. The "early and the later" rains of Palestine still continue, and the Jordan overflows in February now as it did in the days of Joshua. Statistics show that rainfall in New England is much what it was before the country was denuded of its virgin forest. According to Professor Hazen, the well-known American meteorologist, in an address to the American Forestry Association at Nashville, Tennessee, observations made on the rainfall of forests and cultivated ground in France and Germany show that the difference between them is almost, if not quite, inappreciable. Professor Blandford found that a forest tended to give 2 per cent. more rainfall than open ground, and that is regarded by Professor Hazen as inappreciable, since it only means one inch more of rainfall on 50 inches in the year. It is observable that heavy clouds drifting over a plain sometimes precipitate over a forest, and that moisture often hangs above a wood.

The tea market.

Indians.—Of the 58,672 packages catalogued for public sale this week, says the *P. M. Review* of 15th January, about 44,000 were submitted to auction on Monday, the largest number recorded in a single day. To deal sufficiently with this quantity necessitated the tasting and valuing of a thousand samples, and this could have been satisfactorily accomplished had the samples been obtainable at the bonded warehouses when the catalogues were issued. This, however, with few exceptions, was not the case, and prompt steps should be taken to bring the matter under the notice of the merchants, who are, or ought to be, principally interested in the subject. It was arranged some time ago, and partially carried out, that each catalogue when issued should have printed on it, "These teas are ready for sampling"—an arrangement which, if properly carried out, would be a convenience to the trade, as the teas would, in that case, receive more careful attention, and both labour and expense would be saved. The market, on the whole, has been steady considering the quantity offered, which is attributable to the improved

demand, and the more general disposition shown by buyers to replenish their stocks from the excellent value of many of the teas now available. The only descriptions showing irregularity were the poor liquoring low and medium sorts, which have favoured buyers. These bid fair to be ample to meet requirements, but for the more useful teas of the same grades it is not at all improbable there will be a firmer market later on. The better kinds are not too plentiful and have fetched quite former prices, while the finest sorts are in comparatively limited supply, and have sold at hardening rates.

Tea-sweepings: nett weighment & bulking.

The Managing Director of the Assam Company has written to the Indian T. A. as follows :—

"I am much of opinion that the large quantity of tea-sweepings now imported tends to lower the value of dust, and looking to the fact that we can now obtain no more than 2*d.* per lb. for sweepings, leaving us certainly not more than 1*d.* per lb. net, it is pretty clear to me that if all growers would cease shipping this stuff, we should be the gainers, inasmuch as there is a good demand for theine, and if the manufacturers cannot get our cheap rubbish, they must come to the market and compete for dust.

" Please consider this, and see if you can get the views of other shippers."

After some discussion, the Secretary was instructed to write to the London Secretary, and request him to forward particulars as to the demand in London for dust and the amount of dust and sweepings respectively imported.

In his letter of 3rd December, the London Secretary stated that his Committee had tried in the past to introduce a reform in the system of net weighment, but their efforts had not been rewarded by any permanent improvement in the system of weighing tea in the warehouses. They would, however, give due consideration to the question again, in view of the expression of opinion entertained by the General Committee.

He also stated that a meeting of members had taken place, and in consequence of the views expressed by those present, the following resolution was passed unanimously, *viz.*, "That the Association regrets that it does not at present see its way to induce members to conform to any general rule in the matter of printing the place of bulking, and that members be left to act as their interests may suggest."

Jamaican cacao.

Considerable surprise, says an exchange, has been caused in Jamaican trade circles by the English Government sending a telegram inviting tenders for the supply of West Indian cocoa. The incident is regarded as unparalleled in West Indian affairs, and it is expected to have a favourable effect upon cocoas from those regions as against Guayaquil cocoa. The general opinion is that, owing to the stringency of the markets, the Government believes cocoa may be bought more cheaply by tender than through ordinary channels. It is possible, however, that the motive may have been, also, to give practical help to the West Indies in view of the late Sugar Commission's report. As to whether Jamaican planters are fully prepared to take advantage of this opportunity we leave our readers to judge from the accompanying figures. In 1896 the cocoa crop in Trinidad was valued at £452,000, and that was considered to be a short crop in Trinidad. As a West Indian cocoa producing colony the next in importance is Grenada, and in 1895 the crop was valued at £138,000, but that was an unusually year, for in 1893 the crop reached the figure of £281,(In Jamaica, the cocoa crop of 1896 only reached the sur £17,528. Or put it another way. Whereas in 1887 export of cocoa from Trinidad was valued at a quarter (million sterling, it increased to £620,000 in 1895. In 1 the Jamaica cocoa crop was worth £10,000; last year it only advanced to £17,000 So while the cultivation cocoa in Trinidad had increased to nearly three times first quantity mentioned, and that notwithstanding depression of prices, the export of cocoa from Jamaica not doubled as compared from 1885 to 1896. Jamaic had better recall to mind the proverb about putting their eggs into one basket.

Tea-thirst in New Zealand.

In a special description of she shearing in New Zealand—with hands employed on a Canterb station—published in the *Globe*, the following appe regarding the day's refreshment and hours for resti We may remark by the way that the non-advance Indian teas in Australasia must be a great deal due to fact that "billy-tea" is always boiled. Indian tea is strong for such awful treatment :—

"At 5 o'clock, the great ten-gallon boiler, commo called "Big Ben," is steaming on the log fire, preparat to the men's tea at 6 o'clock; into this "shearer's tea-po as the cook calls it, nearly 1 lb. of dry tea is thrown. 30 lb. seed-cake has just been taken out of the oven. men's evening meal consists chiefly of meat and bread butter. Their meals and refreshments throughout the are as follows: A pint of tea and a piece of cake at 5 o'cl in the morning, before beginning the day's work; breakf at 7 o'clock, consisting of mutton chops, bread and but and tea; the first "Smoke-oh" at 9 o'clock, when interval of 20 minutes is allowed for rest, for sharpen the shears, for smoking and for the consumption of anot pint of tea; dinner at 12 o'clock, consisting of joints mutton, about twelve in number, potatoes, bread, currant or other pudding, and tea again: the sec "Smoke-oh" with tea at 2-30; the third "Smoke-o with tea and cake at 4 o'clock; and finally the even meal at 6 o'clock, already mentioned, after which no m work is done. The daily consumption of some of the ite of food at the shed amounts to 60 gallons of tea, to m which from 4 to 5 lb. of dry tea are used; two dozen 6 l loaves of bread, and nearly four sheep (that is to say, per week), 40 lbs. of sugar, and from 45 to 50 lbs. of ca So the men do not starve; nor should they, for their w is arduous and requires endurance and skill.

The coffee market.

A note in an exchange sta that fine Plantation Ceylon has lat realised extraordinary prices, peaberry selling up to 151

Although by the publication of the stocks last Saturd says the *P. M. Review* of 15th ultimo, the world's visi supply was shown to have decreased during December 4,870 tons, owing mainly to a falling off in the Brazil receipts; the latter have since been again heavy, and, consequence, a flat tone has been apparent in the termi market until yesterday, when quotations recovered to level of last week. At auction there has been a dull t for all except medium and fine qualities, though prices

ot very materially lower. A further small shipment of osta Rica sold at a considerable advance upon the previous ts of the same mark, and only slightly below the prices btained for the early shipments of last year, but with a etter supply lower rates may again be looked for. East ndia has maintained its value, though there is little demand t present from the home trade for this description.

LETTERS TO THE EDITOR.

EXPERIMENTAL PRODUCTS.

SIR,—I wish to get some black pepper corn for planting, also a couple of thousand sandalwood seeds. Can you oblige me by finding out where to procure the above seeds, and also the method to plant them? Some of your many contributors may very kindly help a fellow-labourer in this field. Does pepper creeper require shade? And will mohwa trees answer the purpose? I mean, can I have the pepper creeper run up mohwa trees without injury to both?

I have got some 2,000 acres of land and wish to stock it with useful plants. Can you suggest any useful and remunerative and quick-growing plants? I shall feel extremely obliged.

SAIFABAD, HYDERABAD, DECCAN,
30*th January*, 1898. } MIRZA MEHD KHAN.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton:—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

P.S.—Will you kindly let me have the name and address of the native gentleman who wrote on Arrowroot in No. 31, Vol. II, of October 30th, 1897, of *Planting Opinion?*

[For the seed required, apply Curator of Lal Bagh, Bangalore. Details of rainfall and water-supply generally, together with class of soil, are necessary before advising experimental products. We have mislaid the address required. Perhaps if the writer of the article comes across this query, he will reply direct.—ED.]

MR. QUARME AND HIS LEAF-DISEASE CURE.

SIR,—I have, as you are aware, declined to make any reference to my proved system for restoring fertility to the coffee tree, and the removal of its necessary adjunct leaf-disease, since the matter is *sub-judice* between a certain body of planters and myself.

As the writer in your issue of the 22nd January last (1898) has made an undeniable reference to me in "Planting Dialogues," I quote it. "You are ready, some of you, to try hair-brained patent schemes of curing the disease evolved by the fanciful imagination of retired planters." I am not aware of any other "retired planter" who has proved the cause of leaf disease.* I have, through the good offices of the U. P. A. S. I., been in communication with I suppose all the Associations.

It is certainly a mean underhand way of attack, and as it is damaging to my interests, his false insinuations, since it is now under consideration, I shall require him to publish in your journal an apology for so groundless statements, for he cannot possibly know my system since the gentlemen composing the "Confidential Committee" signed a deed to be secret in every way.

To give the fullest contradiction to this inference that it was "evolved from the fanciful imagination of planters long out of touch with latter-day planting conditions," I state that in 1872 and for five years after, I experimented on the coffee tree, making notes on them. In 1877 I wrote a memorandum and left planting in 1880. When at home, I gave it to my two friends, the late James Gordon, of Messrs. Boyd and Co., and T. J. Ferguson, of Hinde and Co., now of Messrs. Burnett and Son, Calicut. The former thought well of it, the latter expressed no opinion, but advised my taking up Gold Assaying Metallurgy, &c., which I promptly did.

I paid dearly for the success of my system, for in the crop of 1877-78, I got a "bumper crop" on the plan I based; and as there was a clause in the lease protecting leasor from having his trees "sweated," it put an end to my lease, he getting this bumper crop. This is known on the Shevaroys to planters of the seventies.

I read every planting publication, but am ignorant of any change of method since 1880. I do know that the average crop of South India produced is under one cwt. per acre.†

CALCUTTA,

GENERAL ARTICLES.

PLANTING DIALOGUES.

II.

GREEN wasn't well pleased, I am sorry to say, when the last "Dialogue" appeared in print. The notions he holds in the righteousness of his cause are sufficiently confused in conversation. In print they are too obvious. His boss was hugely delighted, and chaffs me as being Green's friend with having roasted my pal badly. I say nothing, and bet on the winning horse. Besides, for my part—but there, it's for the public to judge, not me.

Jack Bentley it was who started the game this time. We had all been round a couple of well-known gardens in the neighbourhood, and, before tubbing, shop—diluted with pegs and smokes—was the order of the evening.

"Funny thing, you fellows," began Jack, "but we haven't heard Green's tongue for a long time. What is the matter, my boy, didn't you like the look of that coffee we saw on 'Wood' Estate?" alluding to some such stuff that had been dosed chemically out of its skin.

Green replied that on the contrary he liked the look of it very much. For it proved what he had so often urged before.

"That chemicals do good to coffee?" smiled Bentley.

"No. That some planters haven't the least idea how to use chemicals. And very few how to use what you call artificials either."

"And how would *you* use them, then?"

"That is not precisely the point. Why do you prefer cattle manure to any other manure?"

"Why do I prefer cattle manure? 'Cos it's the best going. Your pet scientists declare it's the only perfect manure known, as it contains everything the plant wants. It's bulky too, and lasts a long while. Now your chemicals and artificials act like stimulants, the effect is over at once almost. *That's* why I like cattle manure, my boy!"

"Exactly so. And as you are unable to procure all you need, you are forced, though unwillingly, to fall back on a substitute. Your ideal substitute would be that fertilizer which would resemble cattle the most nearly. You must admit that chemicals and artificials can supply, if a requisite number are used, all that is contained in cattle-dung, except, perhaps, humus."

Here another arrival interrupted what we thought was to be a discussion on the old, old subject of cattle-dung *versus* artificials.

Bob Trent was a 'twixt-and-between man, and staked his whole belief in artificials, with strong reservations on the subject of agricultural chemistry.

"That's right, Green, give it to Bentley as hot as you like. I'll back you up. What were you saying just now?"

"Talking about making a perfect imitation of cattle manure. Let's hear him out."

So Green proceeded. He saw I was on the look out and chose his words.

"A great difficulty in some estates would be to procure the humus. This could be overcome by the careful preservation of weeds, loppings from shade trees, and any green jungle-growth near. To ensure its decay, it should be stored in pits and kept moist. When in the 'cuts-like-butter' stage, which may be hastened by adding certain chemicals to quicken fermentation, it's ready for the next operation. This is simply the addition of chemicals or artificials in such proportions to make it accurately resemble cattle-dung, poonac or nitrates in small quantities for the soluble nitrates in dung, and tannery refuse or more waste for the slowly-decomposing nitrogen in the solid portions of the cattle manure. Phosphates, potash, lime and the other minerals can be added as easily."

"Yes, but how about the cost, and what are the proportions of chemicals and so on, can you tell me that?" exclaimed Bentley.

"No, I certainly cannot, offhand. *That* is the work of an agricultural chemist. I should imagine that the cost would not be more than cattle manure. I am not dee interested in that point, for I think if we could effect same result on the field, it would be cheaper and better every way."

"Bother cattle manure. I've given it up long ago. W the thing is as simple as it can be. Coffee needs so m pounds of nitrogen, so many of phosphoric acid, and so You apply them, and there you are!"

"I cannot believe it so simple as you say, Trent. instance, what is your theoretical dose of manure, I me how much ought you to get in crop, on theory alone?

"Oh, the usual seven cwt., I suppose. But no expects *that* nowadays, with leaf disease and all."

"So a good deal goes to waste then. Does anyone kn why?"

"Of course. It's all the fault of leaf-disease. It's regularly into their constitution, I mean, the *effects* of disease are shown in every seedling. They don't get a show to start with," rejoined Trent.

"I see. You hold that the plant is unable, throu inherent weakness, to take up all the food given it. appears to be a way of shifting responsibility on to plant's shoulders instead of your own, where, allow me remark, it ought to rest."

Trent was inclined to be riled at this, but kept silent.

Green continued:

"I know you think it cheek of me, a two-year planter talk in this way. Have patience a while. You know t coffee wants certain quantities of certain elements. have you found out in what shape the plant prefers the Let us take nitrogen as an example. It can be given many different soluble and insoluble forms. Confin ourselves to the first, nitrogen can be given in the fo of salts of ammonia, nitrate of soda, of potash, lime, That is, pure chemical form. If you use oil-cakes on other hand, the nitrogen is rendered soluble by fermentati and changed by the action of bacteria into nitrates of so Speaking broadly, nitrates are the only form of nitrog that plants can take up as food."

"That's all right. You aren't getting much 'forrade though," rejoined Trent.

"Well, it is fairly obvious that, *unless* the conditions the soil are such as to allow the bacteria to perform th work efficiently, a great deal of the poonac you use must wasted. The writer of those papers on 'Soluble Nitrog and Leaf Disease' in the *Planting Opinion* goes s further than this. Even if you apply ready-formed nitrat you run the danger of their being destroyed or made usel if the soil conditions are unfavourable. I know you sc the idea of 'wasting' money on agricultural chemist but let me ask you a plain question. If you admit proven the statement that soil conditions command in large degree the fertility of a soil—and any primer agricultural chemistry will bear me out,—how can y know what to do without expert assistance?"

Trent remained silent.

"Don't you see what I mean? I mean that you a almost every other planter in South India, and in Ass and Ceylon, too, are just wasting a tremendous lot money every year, throwing it away blindly. Can y afford it with our wretched crops and dropping prices? one of the last numbers of *Planting Opinion*, there w an article on superphosphates. It gave a good instance

ow ignorance could cause a grave loss. Ignorance is navoidable, but when nothing is done to remove it, it is erily unpardonable!" Green sat down with a flushed ce, for he had risen in the excitement of the moment.

Bob Trent looked unconvinced and said so. Bentley was rofoundly uninterested, as were most of the others.

"No go, Green. It's clear science wasn't meant for lanters. You'ld better get into your tub" quoth one of ne creepers.

FERTILIZATION OF THE COFFEE FLOWER.

II.

With one or two new species of coffee at one's disposal, nd a like number of distinctly marked varieties, such as ne "Maragogipe," which is an introduced variety (from Brazil) of *Coffea arabica*, an experimental plot could be tarted on the following lines:—

(*a*) Situation, as regards aspect, soil, water and shade, o be the best the estate can afford. Occasional irrigation vill possibly be required to induce the different bushes to lossom together, so that the possession of a perennial vater-supply would be a convenience.

(*b*) The crossing-plot need not exceed one-eighth or at reatest one-fourth of an acre in extent, while it is possible hat equal results may be obtained by working systematic-lly on a few bushes.

(*c*) In planting up the crossing-plot, an equal number f healthy seedlings of the estate coffee should be thoroughly nixed with the new kinds, so that winged insects may ave full play on the whole. But in addition to the eneral and haphazard operations performed by the in-ects, a few bushes should be carefully isolated for hand-ertilization. For the latter purpose a few skeleton frames overed with fine muslin would be a sufficient protection, if laced over the bushes before the flowers opened. Plant n a square plot at 6 × 6 feet, so that air may circulate round the bushes freely. The preliminary details which have emphasised under the sub-headings *a*, *b* and *c* will eep the planter employed for at least two years, or, to be trictly accurate, until a maiden crop of flowers is produced n the crossing-plot. Then, at this latter stage, the work f fertilization will actually begin, should several distinct kinds of coffee flower simultaneously. Unprotected bushes will be pollinated through the agency of insects chiefly, while the protected ones will be self-pollinated, should no precautions be taken to prevent it. Where bushes are intended for hand-fertilization, it will be necessary in the early stages of reproductive growth to rub off a great many of the young flower buds, so that the inflorescence of an individual may be reduced to a manageable number of flowers. For that matter, the flowers could be reduced to what is borne on a single primary, or to a few clusters of the same. The necessity for this apparently ruthless treatment is contained in the fact that, during the short time the stigma is receptive of foreign pollen, the fertilizer could only pollinate a limited number of flowers with any degree of certainty. It is, therefore, wiser to make sure of getting a few good crosses than to attempt a larger number indiscriminately.

Let us now suppose that the operation is about to take place. Having provided himself with the marginally-noted requisites, and selected a protected bush to become the seed-bearer, the fertilizer places himself under the protective frame and eagerly watches for the opening of the first flower. Directly the flower opens (usually early in the morning), there will be seen, slightly projecting from its delicate white throat (tube of the corolla), a bifid or two-horned stigma supported by 5—7 arrow-headed anthers on short stalks. At the time of opening, the stigma, which is seen well in advance of the anthers, glistens with a sticky substance which holds fast any powdery matter, such as pollen, that may fall on to it. What the fertilizer has to do at this stage is to dust a little foreign pollen on to it by means of his camel's-hair brush. This done, he instantly, and as deftly as possible, cuts away the 5—7 anthers behind the stigma. But as the anthers are usually closed at this early period, they could perhaps do no harm if they were left. Everything would depend on the behaviour, so to speak, of the stigma towards the new pollen by which it has been fertilized.

A fine camel's-hair brush; small, sharp penknife; small, sharp pair of scissors; pocket lens; flowering branch from male parent, with pollen.

The process as described above has to be done with every flower until the primary or clusters of flowers reserved for crossing have been exhausted. A register is then made of the parentage on both sides, and after a day or two the bush is liberated from its protecting covering.

I have examined many coffee flowers at the moment of opening; in most cases the stigma projects in advance of the anthers and the style lengthens rapidly. By this means the spreading horns of the stigma afford a good platform for small bees and other insects to rest upon when searching for honey. Then flitting from one stigma to another they deposit quantities of pollen which readily adheres to their hairy limbs.

LIBERIAN COFFEE IN THE STRAITS.

INTELLIGENT planters always take an interest in the methods of cultivation of coffee adopted in other countries, especially where the results, in crops at least, are so excellent as those obtained in the Straits. We purpose, therefore, reprinting the most interesting of a series of articles on Liberian coffee, originally published in the *Selangor Journal*:—

FELLING, BURNING, LINING, HOLING, FILLING.

If you can make a contract to burn and clear with the men who fell your jungle, you will save yourself a good deal of money and much time. If the contractor has to clear and burn the jungle, he will be more careful in felling it; he will first clear all the undergrowth, then cut all the branches of the big trees which have been felled and heap them on to the main trunks of the trees—this, done properly, will save him a lot of time and trouble afterwards when he wants to burn it. If he has only contracted to fell your jungle, you must watch very closely that he does all the above, otherwise, you may be snre, he will simply cut the big trees and never trouble himself about anything else. He will also cut the trees as high as possible above the ground, as the trunk is not so thick higher up as lower down ; you should, therefore, stipulate that all trees should be cut not higher than six feet from the ground, otherwise refuse to accept the work or to pay for it. If the above is not regarded, you will have no end of trouble in cutting the small stuff afterwards and heaping it on to big trees : every inch of ground you will have to recovered with axe and parang, and day after day your men will be hard at work at it—yet you will see hardly any progress. Many young planters will not thoroughly dry, but too soon give the order to set fire to it. If this should be the case, they will be very sorry for it afterwards.

Here, again, the coolies will attempt to impose on the inexperience of their young master, and will want him to pay a few dollars for matches and torches. If he tries it himself, he will soon find out that a box of matches does not go far in setting a jungle on fire. But don't pay a cent! There are any amount of bertam trees in the jungle, and a few branches tied together will give the best possible torch for the purpose.

If your wood is properly dry you will have a good burn and will be able to proceed at once with lining and holing, but if you have been too hasty in setting fire to it, or if you have neglected to see that the jungle was properly cut and the wood properly heaped on, you will have to work a few weeks, or perhaps a few months, after the burn to clear the ground of the remaining wood.

Of course it will all rot away in a few years, and probably in five years it would disappear by itself; but in the meantime it will be in the way of your drains and your roads ; and, what is still worse, it will be an attraction for white ants, who, after they have finished all the old wood, will be obliged to starve or to eat your nice coffee trees, and, you bet, if they have to choose between the two, they prefer the coffee trees.

Lining.—I think it is now generally recognised amongst planters in Selangor that the proper distance for Liberian coffee trees is 10 ft. by 10 ft. Some planters think it unnecessary to line their clearing regularly in every direction and think that it is quite sufficient if the lining is done in one direction only. No doubt the trees will grow just as well in one direction as in the other, and, as far as that is concerned, you need not line them at all, but plant in every direction—as long as they are only sufficiently apart from each other. But to every good planter this would be at once a sign of bad and careless management; bad lining will remain an eyesore for ever, good lining a credit to the estate and its manager and a source of continual pleasure and satisfaction to the planter. It will show the coolies ot once that you insist on order and systematic working, and it will make them careful in the execution of their own work too. Good and regular lining facilitates the control of your work, makes it easy to approach every tree and easy to overlook the plantation and to detect the slightest irregularity. Most of the planters use small wooden pegs for lining. I do not see the advantage of this; they cost more than *anakkayu* (sticks) and cannot so easily detect any irregularity as you can with sticks a 4 to 5 ft. long. A man will cut 150 to 200 of such sticks in jungle as a fair day's task. The lining is done with a rope ma every 10 feet with a piece of coloured cloth. Two men get ho this rope, one at each end, and other coolies walk along the and push a stick into the ground at every 10 ft.; one line b finished, the two end men, who each have a stick 10 feet in len measure the distance to the next row and put an *anakkayu* in ground in the exact continuation of the direction of the former li and then the other coolies again walk along the rope and put d the other sticks, and thus the same process is repeated with next line and so on. The sticks can always be used again.

Holing.—Before you plant out your young coffee trees, i necessary to prepare the ground for their reception. The gro being lined, you can start at once with holing. The holes sh be 2 ft. square and 2 ft. deep. It does not matter so much if t are only 18 in. square, but they should not be less than 2 ft. d especially in stony soil. The reason for this is, that if the yo plant grows and develops, you can always help its development digging up the ground around the tree as it grows, but of cours is quite impossible to do anything to the tap root in the ground, if the tap root grows up to the end of the hole and meets the st soil, it will not be able to grow any further; it will bend, double get crooked, and the tree will remain a sickly miserable thing never give you the rich return you are expecting.* A cooly will from 50 to 60 holes 2 ft. deep by 2 ft. square in a day, accordin the nature of the soil; in rocky soil he might, however, not be abl cut more than 10 to 20. As soon as your holes are ready, you begin to fill them.

Filling.—Many planters think that it is necessary to leave holes open for some time—to let the ground get cool or for s other unknown reason; but there is no justification in this. might just as well dig the holes and fill them in again at once; in that case your coolies would scamp their work and you would be able to control it, nor able to convince yourself that the h have been cut wide and deep enough. Therefore the filling u done only after holing is finished and has been received and accep by the planter. The hole is filled now with top soil, not again the same soil that has been dug out, and the earlier you fill the h the better. If the holes are exposed to the sun for any lengt time the sides get dry and hard, and that's just one of the v things you intend to avoid by digging holes. In cutting holes d allow your coolies to touch or to remove the pegs. If that is done they will remove the pegs, and in replacing them they will put them back in the exact place again, and the result will instead of a regular good lining, a disgusting zig-zag.

(*To be continued.*)

* Java planters don't agree with this. In a coffee garden of about 20 t years of age, at Pengalenggan, planted on rich virgin jungle, some trees transplanted with the utmost care. Not one of them had the tap root deepe the ground than 6 to 8 decimeters, whilst surface roots were developed so m stronger. There could be no question of the lower soil not being equally adapted for these roots ; but it may be that a less careful planting out origin forced the tap root to a deviation and to shoot out branches. Whatever th may be in this, it proved beyond any doubt that the undisturbed growth of tap root, as such, is not indispensably necessary for a strong development of coffee tree up to a high age. ("De Oost-Indische Cultures," by K. W. Gorkom, Amsterdam, 1880.)

DISTRICT ASSOCIATIONS.

NILGIRI PLANTERS' ASSOCIATION.

A GENERAL meeting of this Association was held at the Maso Hall on Saturday last, which the following members attend namely, Messrs. E. G. Windle (*Honorary Secretary*), Cockbu L. W. Grey, J. H. Pascoe, H. J. Wilbraham, Rhodes Jam J. W. Minchin, Barber and Marden.

Mr. Rhodes James was called to the Chair. The proceedings of

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

eeting were read, and the Honorary Secretary then informed the eeting that the proposal to employ an Agricultural Chemist had llen through so far as this Association was concerned. He had ceived a letter, he said, from the Secretary of the Shevaroy anters' Association, proposing that that Association should join e Nilgiri Planters' Association in this matter. This Association d subscribed 2,100 rupees towards the project and, in so doing, had rhaps done all that could be expected of it. One planter, it would pear, had suggested the idea of getting a chemist altogether for emselves, and had sent round to sound some of his friends on the bject, but the measure of success that had attended his efforts was known. In such a matter as these, this who did not join would ap the same advantage as those who did—and this would be unfair. The next subject on the Agenda was the Lady-bird Fund. This ssociation had subscribed Rs. 2,125 towards it, which had already en remitted to the U. P. A., and the fund was fairly well supported. he Honorary Secretary said he had a letter from the Planting ember telling him that Government was prepared to give Rs. 2,000, d that all necessary arrangements had been completed for r. Newport to go to Australia, and that his passage by the Orient he had been secured. From Mr. Newport himself a letter had been ceived enquiring if he was to despatch consignments of lady-birds fetch them himself; also whether he was to make arrangements r the despatch of further consignments, after he left Australia, and the event of this latter enquiry being decided in the affirmative, whom such consignments were to be addressed. The Nilgiris, it as thought, would be the best place to which to bring the lady-birds, they are in touch with all the South Indian planting districts, t as it would be necessary that Mr. Newport should be here, too, ll they were distributed, and that it would be an expensive business, was decided that he should, in the first instance, proceed with em to the Pulneys, his own home. An additional advantage of the lneys would be that the efficacy of the lady-birds would be tested a locality where the green bug is more destructive than it is on e Nilgiris. Mr. Pascoe offered to place a bungalow at Woodlands the disposal of Mr. Newport in the event of it being decided to ake the Nilgiris Mr. Newport's headquarters.

The Association accordingly resolved to reply to Mr. Newport, to e effect that he should personally convey the lady-birds to India d take them in the first instance to the Pulneys, and that arrange- ents for subsequent consignments should be deferred till it was en how the first instalment turned out.

Counsel's opinion on the Contract Forms applicable to Act XIII. 1859 it was reported had been asked and paid for, but not yet ceived.

The Honorary Secretary passed on to the correspondence that had ssed with the Superindendent of Police on police supervision during e coffee season. That officer had complained of the insufficient formation on certain passes that covered consignments, and desired at all matters required to be noted on the pass should be so noted ensure efficient check of coffee in transit.

The nomination of the Planting Member of Council was next pro- eded with. The Hon'ble Mr. Hodgson had refrained from attend- g this meeting to allow it the freest discussion on this subject. The nited Planters' Association of Southern India had expressed a hope at Mr. Hodgson would come forward again, and this Association as of the same opinion. Accordingly Mr. Gray proposed, and Mr. hodes James seconded, that the Hon'ble Mr. Hodgson should be commended for another term of office.

This brought the business to a consideration of Mr. E. R. indersley's two propositions: (*a*) That all growers of coffee under a rtain acreage, say 10 acres, should by law be bound to produce the ffee they have for sale before some responsible person in their own mediate neighbourhood and obtain their passes for the coffee from m. (*b*) That the extent of their holdings should be registered and, if ssible, an estimate of their probable crops made before crop time.

The discussion that ensued did not show that members believed in the possibility of Government accepting these suggestions, but as the Coffee Stealing Act was in its hands at present for amendment, it was resolved to forward Mr. Kindersley's proposals for incorporation in the provisions of the amended Act. The Chairman moved this resolution and Mr. Minchin seconded it.

The last subject considered was a letter from the European and Anglo-Indian Association regarding proposed amendments to the Criminal Procedure Code. The letter was recorded.—*Nilgiri News.*

Correspondence and matter for publication to be sent to ditor, this paper, Coonoor.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (January 21, 1898) says:—Rather larger supplies were brought forward in Auction this week; the demand however was slow and values ruled generally in buyer's favour except for a few colory parcels of new crop which attracted good competition.

No East India was offered.

Columbian which formed the bulk of the catalogues sold slowly at 1/- decline for ordinary descriptions but colory lots were easily disposed of at full prices, whilst fine new crop Costa Rica realised extreme rates.

Futures after some slight fluctuations close 6d. to 9d. lower than last week, but business has been very quiet. Messrss. Naumann and Gepp estimate the next Rio crop at $2\frac{1}{2}$ to $2\frac{3}{4}$ million bags.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending January 19th, 1898, says:—Bank rate 3°/₀. Bombay Exchange closes at 1s. $4\frac{1}{16}$d. Brazil Exchange $6\frac{13}{16}$d. Rupee paper $3\frac{1}{2}$ °/₀ $63\frac{3}{8}$. Silver $26\frac{1}{8}\frac{1}{1}$d. per oz.

Continues dull for all kinds except fine, which meets with a ready sale; gray and ordinary qualities have mostly been bought in. Fine Plantation Ceylon realized extraordinary prices, peaberry selling up to 151s. Brazil markets continue flat.

The next Dutch sale will take place in Amsterdam on the 25th inst., when 30,765 bags Java, 40 packages Padang, 1,500 bags Menado, and 40 bags Sumatra will be offered.

Daily receipts averaged 8,100 bags in Rio and 14,100 bags in Santos.

Futures show a slight advance, closing quiet, viz.:—Good average Santos in Havre, March delivery, fcs. 37·75, in Hamburg pf. 31, and No. 7 low ordinary Rio —, in New York $5.80.

To-day's London official quotations are:—

	Jan.	March	May	July	Sept.	Dec., '98.

Planting in Java and Ceylon	76

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 25th February, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nilgiris. COONOOR, 15*th February.*—*Weather.*—Very rainy the whole week; one or two regular plumpers. Cleared up this afternoon, but still overcast at night. *Crops.*—Coffee wants a little sun and the remainder of crop will be in with a rush. Spike very forward and a splendid early blossom seems fairly certain. The rain will be grand for tea and should force out a bountiful March flush. *Labour.*—Ample enough, as usual.

Kadur. MUDIGERE, 14*th February.*—*Weather.*—Fine but cloudy, so much so that on the 11th many predicted rain, which is not wanted now. Clouds have passed away and the planter is happy. *Labour* is plentiful, and many estates are paying coolies off. Pruning has been delayed till *after* the blossom showers, which, for many reasons, is the most reasonable one. *Interesting Items.*—The Rev. C. H. Wright held Divine Service at Moodsoosy on the 9th. There were ten present, and a collection made in aid of the Additional Clergy Fund. A sad accident occurred last month, when a young planter shot his shikaree, who died almost immediately. The annual meeting of the South Mysore Association is to be held at Belur on the 3rd March. As the meeting is to be held for two days, it is a pity that a more central and a more convenient place has not been chosen. Price of cardamoms Rs.70 a maund; coffee Rs.10 a maund.

Kil Kotagiri. NILGIRIS, 15*th February.*—Rain has fallen since Wednesday night and has done considerable damage on the estates. No rain has fallen in February for the last twenty years so incessantly or so heavily. On Wednesday night the rain was 5·83 in.; ·12, Thursday; ·38, Friday; 1·45, Saturday; 6·65, Sunday; 4·25, Monday. Total for six days, 18·68. The wash caused, especially on young

clearings, is very bad, the last two days' rain doing all the damage. One nursery that has been used for twenty years has been swept clean out, carrying both coffee and shade seed beds away, the water running 6 ft. deep over the beds. It is still raining. *Labour* fairly plentiful. *Grain* very expensive.

Coorg.

POLLI BETTA, 16*th February.*—*Weather.*—Some drops of rain which fell on Friday last, the 11th, in the evening served to make us very apprehensive; but I am glad to say it proved a false alarm. It clouded up somewhat yesterday again. There has been heavy dew on some nights. *Crops.*—Gleaning still in hand. Spike of coming crop somewhat forward, but fresh and healthy. *General Health.*—Same as reported last week. *Interesting Item.*—Rifle meeting arranged for early in March.

S. E. Wynaad.

DEVALA, 16*th February.*—*Weather.*—Since my last report there was no change in the weather, except all yesterday it was very cloudy and at about 3 P.M. there was slight drizzle; at night it rained very heavily for about 2½ hours. To-day partly sunshine and partly cloudy. *Crops.*—Last night's rain brought the spikes forward. Paddy harvest is finished and the ryots have begun ploughing. *Grain.*—Salt 8, rice 8, cholum 9, and ragi 16 seers per rupee. *Health.*—Fever. *Labour.*—Sufficient.

Nilgiris.

KOTAGIRI, 17*th February.*—*Weather.*—January cold; crop dragging and coming in very slowly to make up deflated estimates; one appreciable shower of ·25 in. on eclipse day; total for that month ·70 against average due 0·47 in. It was hoped that rain would hold off, but it has been coming down in buckets since last Friday, upwards of 18 in. falling in three days on the coffee half way down the ghaut, of which as much as 8·25 in. was recorded in twenty-four hours; it was heaviest to the eastward, notably Kil Kotagiri side and lighter higher up the ghaut approaching Kotagiri; still the rainfall recorded at the 8th mile down the ghaut has been on the 10th, 4·85 inches; 11th, 0·08; 12th, 0·25; 13th, 1·80; 14th, 7·00; 15th, 1·30; 16th, 1·80; total, 17·08 inches; whilst in the station itself it aggregated only 5·23 in., the heaviest fall, on the 14th, in the 24 hours gauging only 2·68 in. Clearing up to-day, and although such early rain is much to be deprecated, most places, especially Kil Kotagiri side, where crops have been very short and early, were very forward, and this heavy downpour will everywhere bring on balance of crop on the trees and in most places bring out a great show of flower. Ghaut road messed about a good deal. *Interesting Item.*—Annual regimental rifle meeting over before the rain; nothing "big" on in individual scores; team put together 392 points for Bates' challenge cup, beating Coimbatore by two points only. Other companies go one better.

HONEY AND ITS PRODUCTS.

IN the last fifty years immense progress has been made in bee-keeping or agriculture, as it is termed scientifically. The three products of agriculture are honey, wax and "propolis." Centuries ago, the trade was considerable, and held of far more importance than now. Wax was largely used as an illuminant; honey was the only substitute for sugar, besides being largely used in medicine. The Reformation and the introduction of cane sugar joined hands in dealing a severe blow at the trade. Mr. W. A. Harris, in an interesting paper in the *R. A. S. E.* Journal, asks, and answers, the question: what is honey?

Honey, as we know it, is composed of two kinds of sugar, named dextrose and levulose, with slight admixtures of pollen and formic acid. It is stored by bees for their winter food and for the nourishment of their young, being extracted from the nectaries of flowers, which in many cases depend entirely on this act for the fertilisation of their seed. Hence the oft-reiterated importance of having prosperous stocks of bees in the immediate neighbourhood of fruit plantations. If these stocks are at a distance, and it happens that cloudy weather prevails during blossoming time, the bees will not be able to do their work, for it is only in the finest weather that they venture to any distance from their hives. Mr. deChampville includes bees among our allies against plant parasites, inasmuch as that in collecting pollen the bees expose the eggs of the parasite, and arrest development or cause them to fall.

Apis mellifica, the "honey-bee," stands alone in the great order of Hymenophera in the enormous quantity of honey it can be made to supply under domestication. As much as two cwts. of honey have been obtained from a single hive in a season, while last year there is an authenticated instance of a yield of 334 lbs. taken from one stock. This is of course phenomenal.

Honey is justly esteemed as an article of diet, for it is the most digestible of all sugars. Sugars, fats and starches supply the chief materials for the evolution of energy and keeping up the heat of the body. The rate at, and manner in which, these compounds are assimilated by the blood vary greatly. Fatty matters must be acted upon by certain secretions before they can be assimilated at all. Starch matters are likewise insoluble until converted into sugar. Sugars, however, can almost immediately be dissolved and taken up. Of sugars there are, however, two main classes, cane, or sucroses; and grape and fruit, or glucoses. The former must be converted into the latter before they are available as food. Now nectar consists mostly of cane sugar, but it is partially digested in the crop of the bee and is converted into glucose in the shape of honey. Thus many people, who on account of the derangement of their alimentary organs, can digest neither fat nor cane-sugar, find no difficulty in assimilating honey. Honey never turns rancid and will keep for years if under warm and dry conditions. Compared with butter, it is little more than half the price of the best fresh butter.

Its taste depends greatly on the sources from which the nectar is obtained. White clover, sainfoin, lime or linden, fruit trees of all sorts, and lastly heather, all give their distinctive taste and aroma to the honey made from them. Honey is marketed in two forms, as "comb-honey" or "extracted." Many people prefer the former for two reasons; first, that it is bound to be genuine; secondly, that it is "ripe" (if sealed over). When honey is freshly deposited by the bees, it contains an excess of water. Unless this water is allowed to evaporate, the honey will ferment. So the intelligent insects, before sealing the cells with wax, allow a few days to pass to allow of the necessary escape of water. "Extracted" honey is obtained by ejecting it from the combs by centrifugal action in machines made for the purpose. The combs are often made artificially, and when emptied of the honey are replaced in the hives, to save the extra labour the bees would have in building the comb. Some authorities state that 16 lbs. of honey are used for the elaboration of 1 lb. of wax. So the saving in "extracted" honey is thus considerable.

Its medicinal effect is undoubted. It is a mild laxative

mixed with lemon or lime-juice it is very useful in cases of relaxed or sore-throat, in quinsy and tonsilitis. As a plaster for boils it has been in repute for ages.

As a beverage, mead, it is little known nowadays, except in the country. Yet if properly made, it is a most agreeable liquor, being in fact superior, both as regards flavour and wholesomeness, to many of the light foreign wines. Careless manufacture has ruined its former reputation. In our next issue we shall give recipes for the preparation of the different meads that can be made. An excellent vinegar, or melegar as it should be termed, can also and is being manufactured from honey. It has various advantages over ordinary vinegar, such as not staining silver or linen; it is also recommended by doctors and dentists to those who cannot take the common corroding vinegar.

Adulteration in foreign honey is largely practised; English honey has so far kept its name intact, while the French article has also an excellent name.

Wax is not, as is generally supposed, formed from the little coloured balls of pollen carried on the bee's hind legs. It is a carbohydrate, related to oils and fats, secreted in small pockets or sacs, four on each side of the abdomen of the insect. Wax is used in the manufacture of the "comb-foundation," which is one of the mainstays of modern manufacture. It is, unluckily, often adulterated with deleterious substances which results in the bees refusing to work on it. As an illuminant, it is still used to a considerable extent, not only for candles but for tapers and "vestas." The fact of wax still being so cheap is explained by the large imports from foreign countries where it is gathered in the forests.

The third product of the hive, propolis, is a highly resinous and tenacious material, collected by the bees from the buds of certain trees, notably the large and sticky ones of the horse-chestnut and from many of the coniferal or cone-bearing trees. It is employed by the bees for stopping every crack and crevice, and for sticking the hives to their floor boards. Slugs, mice and other intruders are encased in propolis to prevent putrefaction.

Careful experiments with the English and Italian bee have been made for the past few years on the Nilgiris, but have at last resulted in failure. Honey was obtained in quantity and of an excellent quality, but for some reason or other breeding did not take place. It is possible that renewed experiments might succeed eventually, but we would strongly recommend Anglo-Indian bee-keepers to experiment instead with the ordinary small Indian bee. Modern methods of bee-keeping could be applied almost in their entirety, and a remunerative trade established at a slight outlay of capital. As most of the most successful and enthusiastic bee-keepers in England are ladies, the wives and daughters of planters would find in agriculture a fascinating and remunerative industry.

NOTES.

Ceylon tea estimate. The official estimate for the present year puts the crop at 122 million pounds, an estimated increase of 6 million pounds over last year's crop. Since 1891 the yearly increase has been respectively about: in millions of pounds, 3, 13, Nil, 13, 1, 8, 6.

Coffee and Kola in British Guiana. The cultivation of coffee continues in this colony, but so little enterprise is shown that the quantities produced are little more than to satisfy local demands. It is the same with cacao. Kola is looking up a little and some shipments have been made.

Dentrification and farm-yard manure. In the last quarterly number of the *Journal of the Royal Agricultural Society of England*, there is an able paper by Professor R. Warrington refuting the conclusions of the German scientists on this subject. As we gave much prominence to the latter, we hope to likewise give similar publicity to the other side of the question in a future issue.

Indian patents. We have received a copy of the *Indian Patentee's Guide*, compiled by Mr. H. H. French, Superintendent, Patents' Branch, Revenue and Agricultural Department of Government of India. It will be found of great assistance to any one desirous of applying for patents, the explanations regarding the working of the Act being clear and concise. Copies may be obtained from the compiler, at 11, Marsden Street, Calcutta.

Coffee planting in Burma. We cull this from an exchange. It is presumed that the concessions will not extend to Europeans:—"Government experts have reported that there are excellent prospects for coffee-growing on the Toungoo Hills, Burma. A few European planters have already succeeded beyond expectation. The Commissioner of Tenasserim has intimated that advances will be made to Burman and Karen planters who settle on the hills with the intention to grow coffee, and it is anticipated that this offer will be largely taken advantage of."

Lime in bones. Though the lime in bones is of value in sweet, well aerated soils, it cannot replace the action of caustic lime in sour wet soils, as it is a neutralized body. On these soils, lime should be applied in its caustic state, *i.e.*, should be burned on the estate. As soon as possible after burning it should be applied as a surface dressing, and lightly worked in. By this mode the chemical action of slaking goes on in the soil, the moisture being drawn from the soil instead of the air, and the lime, bursting in the soil, becomes perfectly mixed with the latter.

Paddy straw in nurseries. The usual thing in these parts, writes an Assam planter to an exchange, is to put paddy straw lightly over the earth so as to retain the moisture when the seed is planted in the nursery. If paddy straw cannot be got, old thatch is the next best, but paddy straw is out and away the best. The paddy straw seems to cling to the earth better, and is far softer, and seems to dissolve in a sort of way just when it is not wanted as the young plants begin to show above the earth. The thatch always seems to be standing away from the earth; with the least puff of wind away it goes. Nor does it retain the dew so well.

Rubber on the Nilgiris. Mr. L. C. Grey, Pykara, Nilgiris, has succeeded in producing a very good sample of rubber on his Northern Hay estate, at about 3,000 feet elevation. In a letter to the Nilgiri A. H. Society he gives the report and valuation on the rubber. The variety of tree is Castilloa. The rubber is of good colour, very clean and is quite soluble in benzol; it has no bad odour, and its elasticity is excellent. The sample is similar to some Burmese rubber sent to the Imperial Institute which was well reported on, but, unlike those samples, it shows no disposition at present to decompose and become sticky; value in London 1*s.* 9*d.* per lb. Details of yield, etc., would be welcome. We congratulate Mr. Grey on his successful experiment.

Budding and Grafting Orange Trees. A writer in a Jamaica paper says on this subject that time could be saved in converting the sour orange into sweet, especially in the case of the older trees, if the process of budding were combined with the equally simple one of cleft grafting. For instance, after cutting the stalk to within a foot or two of the ground, the cut surface might be evenly pared, and four or more scions, or slips of sweet orange, at once inserted, plastered and bound up as directed in works on gardening. Even if the scions failed to take, shoots would inevitably spring up from the stump, which might be budded in due course. Cleft grafting has been found to answer with such succulent barked trees as the mango and cherimoyer, so that it would be worth trying the experiment with the orange.

A Useful Hedge Plant. One is always hearing complaints nowadays of the paucity of good plants suitable for hedge purposes. This being so, thanks are due to Mr. A. Tempest, of Parnell, for his enterprise in introducing and propagating the "Kei Apple." It was Sir George Grey, I believe, who first mentioned the shrub, which grows wild upon the Karoo, or sandy plains of South Africa, and it certainly seems a perfect hedge plant. It is a sturdy, stocky, short-jointed grower, an evergreen, and with thorns which grow to six inches long and over, and a "perfect terror to evildoers," be they beasts or human beings. As an added advantage, the female plants (they are of both sexes) fruit heavily, bearing in great quantity yellow plum-shaped fruit, the size of a greengage, which are both pleasant eating and make an exquisite jam. Orchardists would do well to bear this shrub in mind when planting.

Composition of Jadoo. In answering some questions at a lecture given by him at Worthing, in last November, Col. Halford Thompson replied that: "Jadoo is simply peat moss with soot, bone-meal, and gypsum, with a very small quantity of phosphoric acid and potash. These ingredients are boiled together, and then fermented. The whole essence of the success of Jadoo lies in the amalgamation by fermentation in a particular way. We make also a liquid, which is much used in France. This is often very useful where you cannot use the fibre, although it has not all the rooting properties that the fibre possesses. It consists of the same components boiled together in a more concentrated form and fermented. You may see from this that there is nothing in Jadoo that can be in any way deleterious. There is nothing in it that can possibly do any harm. Of course, if the stuff were ba made or badly fermented, you might get the soot in a cr form, but as we make it the soot entirely vanishes amalgamates. It is on proper fermentation that the wh process depends."

Distilling of Essential Oils. Among the methods employed small flower-farms for the distilla of essential oil from flowers herbs are the following:—Place the cleanly-picked pe or herbs in a bag, which is suspended in boiling wa The bag must not be allowed to touch the bottom of copper, or it will give a disagreeable tarry flavour to soil. The steam from the boiler is condensed in the us way by passing it through a worm, which is kept cool means of running water. The liquid that comes out of worm contains a thin film of oil, which is allowed accumulate in a reservoir till it can be drawn off by a

To manufacture attar of roses, the best varieties *Rose centifolia* and *R. sempervineus*. The petals shoul carefully separated from the salyx and then placed i glazed earthen jar, into which pure spring water is ad till the petals are covered. The jar should be exposed the sun for a few days, and the resultant film of yellow gathered by gently soaking it up with cotton wool squeezing it out into a phial.

The ordinary methods of distillation can also be emplo

Brazil coffee prospects. Rio de Janeiro advices, states *H. & C. Mail*, to December 28, that the weather had been very favourable to the grow coffee crop, having been warm, with occasional rains. *Rio News* of this date reports as follows on the mark "The week, or the five working days, past was ac again, with total sales estimated at a little over 100, bags, of which nearly 60,000 bags were declared on 23rd and 24th inst. The receipts have continued on same scale, and the decided decrease in the supply by and barra dentro is neutralised by the coastwise entr which seem perennial, but the shipments have ag exceeded the receipts, and the market has been stea maintained at 12 dols. per arroba for No. 7, until on the 2 some brokers advanced 200rs and others 400rs per arr What sent the exporters into the market for 40,000 b on Christmas eve we did not discover, and the publis advices from the foreign exchanges furnished no expla tion, but the movement strengthened dealers and fact some of the latter having previously shown a little nerv ness, although always disinclined to entertain bids un 12dols."

"Dead" Fertilizers. In the last annual report the Hawaiian Sugar Planters' A ciation, Dr. Maxwell states: "Our upland soils contain 0·5 per cent. of nitrogen; but the crop results are evidence that these 20,000 pounds of nitrogen per acre not available for plant growth so long as certain of mineral compounds remain in their present state. C vation, and the application of small quantities of lime quently (500 to 800 pounds every two to four years), will before other means, in the amelioration of such soils preparing them to be fertile. These observations do apply, at least to anything like the same measure, to

owland soils, whose difference from the uplands we have welt upon in previous reports."

Again, in commenting on the undue presence of iron in ne soil, the same gentleman remarked that the phosphoric cid of the iron soils were so locked up by the iron and ther bases present, that plants could not use it without reat difficulty. In fact, in soils containing over 12,000 lbs. f phosphoric acid per foot acre, not 20 lbs. were available. Nitric Acid" will herein find additional confirmation of is interesting theories.

---

he Tea market.

Indians.—The public sales have again been large, viz., 62,649 packges, establishing another record as compared with the upplies offered in any previous week, states the *P.M. Review* f 22nd ult. This heavy quantity following the large offerings f last week has caused some irregularity in values, especilly in the poor liquoring sorts of both whole and broken eafs. These have been largely offered, especially the roken sorts, and, being in excess of requirements, it is by o means certain that prices have touched the lowest point. t is generally the case when leaf teas are reasonable in rice, and practically as good in cup as the broken kinds, hat the latter are comparatively neglected, the trade prefering the former, as the appearance of the blend is more niform. At the same time, broken leafs generally have allen to a level which will doubtless eventually have a timulating effect on the demand, and a much larger usiness may be looked for. The medium and lower grades giving a good infusion have been readily bid for at prices arying little from last week, with the exception of an ccasional slight advance on teas of the same marks sold reviously. The next better descriptions have sold steadily, he supply being sufficient to meet requirements, while the inest sorts, the quantity of which is gradually getting into small compass, are difficult to obtain on former terms. Of he 62,649 packages brought forward at the public sales 7,030 were withdrawn, mainly consisting of Calcutta-bought eas.

Spices.

No business of importance has transpired this week in black pepper, ut quotations have been firmly maintained, says the *Grocer* of 22nd ult. Limited sales of Singapore for arrival have aken place at $4\frac{1}{16}d.$ to $4\frac{1}{8}d.$, and on the spot at $3\frac{7}{8}d.$ for air. Only a trifling supply was offered at auction and withdrawn. White pepper has ruled steady, but business is of light amount for arrival—Penang $6\frac{1}{8}d.$ to $6\frac{3}{8}d.$, Singapore $7\frac{3}{8}d.$, Siam $7d.$; also Penang on the spot and near at hand at $6d.$ At public sale 200 bags Singapore were retired at $7\frac{1}{4}d.$ per cwt. Fine Japan chillies went without reserve at 43*s.* per cwt. Pimento continues to advance owing to the absence of arrivals, but sales are of light amount at the increased rates, and comprise ordinary to good at $4\frac{3}{4}d.$ to $5d.$ *Cassia lignea* has had a moderate inquiry at 47*s.* to 47*s.* 6*d.* Cloves have been much less in request, but the market has a steady tone. Moderate transactions are reported in Zanzibar, for delivery March-May to June-August at $3\frac{5}{15}d.$ to $3\frac{7}{16}d.$, and on the spot at $3\frac{1}{4}d.$ At auction common Penang unpicked found buyers at $5\frac{1}{4}d.$, Amboyna $4\frac{1}{2}d.$, and Seychelles $3\frac{1}{4}d.$ to $3\frac{3}{8}d.$ per lb. Great dulness exists for Cochin ginger, only a few lots of 1,700 bags 20 cases selling —small and ends 13*s.* 6*d.*, and ordinary small-cut 32*s.* 6*d.* to 33*s.* 6*d.* per cwt. Mace has a slow sale at the former currency Nutmegs are partly neglected, but unaltered in value. Penang nuts averaging 65 to the lb. were sold at 2*s.* 7*d.*, Bombay 108 to 90 at 1*s.* 1*d.* to 1*s.* 5*d.*, and West India (in shell) 9*d.* to 10*d.*

Peat moss for drying fruit.

The following short note on the experiments in fruit drying, which have come under the notice of the British Consul at Stettin, will be of service to those of our readers who wish to experiment in preserving fruit. We may mention that large supplies of peat can be obtained at very cheap rates on the Nilgiris:—"The manager of a Government peat-moor near Stettin, wishing to keep some apples and pears during the winter months, thought he would try packing them in 'mull'—that is to say, the dust obtained from the dry moss litter when being torn up by the 'Wolff' machine. In this mull, or dust, he packed a number of pears and apples, enclosing the whole in a wooden case, and pressing the mull well down, taking care that each fruit was kept a little distance from the other. At the end of three months he found the pears and apples perfectly dried and as sound as those prepared for commerce by the more elaborate methods, while on being placed in warm water they began to swell out again to their former proportions. Mr. Powell, the Consul, thinks that if further experiments should be satisfactory, there is a possible future in the process. Mull, he adds, sells in Germany at about 1*s.* 3*d.* per cwt., and, as it is exceedingly light, one hundred weight would dry a large quantity of fruit, while it can be used again many times over, has no smell, and does not convey any taste to the fruit. It merely absorbs the moisture which the fruit contains, at the same time hermetically protecting it from the air."

Coffee Rivalry.

The report of the Government of India on coffee cultivation affords another instance of the way in which the fortunes of distant and disconnected portions of the earth are linked together, says the *Globe*. Take coffee. In the heart of India, a circumscribed zone might be marked out, including the districts of Mysore and Coorg, Malabar and the Nilgiris which would be practically the whole of the coffee-bearing region under the Indian Government, and if we turn the terrestrial globe completely round, we shall find a similar coffee region on the other side of the world, in Brazil.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c, contain per ton:—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

In spite of geographical distance, when the naked coolie of Mysore finds work scarce and wages low, he may safely attribute it to the fact that prosperity is smiling upon his antipodean counterpart. This fact is very clearly brought out in the report of the Government of India. From 1876 to 1878 inclusive, Brazil was in political trouble, and the Indian coffee grower made such handsome profits that cultivation rapidly extended. Then came India's trouble in the shape of the coffee-boring insect and leaf disease; and Brazil ruled the market, while unremunerative Indian coffee plantations began year by year to give place to tea-gardens. But in 1889 the pendulum swung the other way once more. Science, says the *Globe*, had defeated the coffee borer and rendered plants immune against the leaf disease in India! *We only wish it had!* While American "corners" in Brazilian coffee and fresh political troubles gradually enabled the price of Indian coffee to rise in 1893 to double the price that ruled in 1885. Brazil is still more or less troubled, its prices, we may add, are now the lowest on record, and the coffee of India still rules high; but assured peace and prosperity in Brazil would promptly send prices down again.

Yield of bananas.

In Vera Cruz bananas are deemed a very profitable crop, the produce all being disposed of at about 1 dollar 25 cents per bunch in the States. The cost of freight, commission, &c., is estimated not to cost more than a dollar, the remainder 25 cents being considered a very remunerative rate. A strictly average crop is put down at about 100 per acre, 300 trees being planted to the same area. The cost of cultivation is very small, as is well known. Three hundred trees per acre is equivalent to 12×12, which is a good distance apart. Only three stems should be allowed to grow per stool at the same time; one, the bearing stem; two, the almost mature stem; three, the young sucker just coming on. The local retail price is about 12 annas or a rupee per bunch; if we allow a reduction of 66 to 75 per cent. for wholesale rates, we arrive at 4 annas a bunch. An acre yielding 600 bunches a year would thus give a gross income of Rs.150 per acre. This is ample enough to cover all expenditure, and yield a high rate of interest on the small capital.

On this basis experiments in drying the fruit for the home market could easily be reckoned out. It would be sufficient to make trials with purchased fruit, taking care that it is of the very finest quality obtainable. If found to pay, banana plantations could forthwith be started. Between the rows of plantains, many other products could be cultivated, such as coffee, cacao, nutmegs, kola, pineapples, &c. These at least for low elevations, while higher up (say from 5,000 to 6,000 feet, which is the limit of elevation bananas can stand) tea, English fruit, jalap and ipecacuanha.

In choosing land for a plantation, it should be remembered that artificial water-supply is a great desideratum. Deep, rich bottom lands and ravines suit the banana well, as shelter from high winds is indispensable.

Selection of seeds.

The following extract from a report of Professor J. C. Arthur, Botanist of the Indiana Station in the United States, will be found of great interest to thoughtful planters. He has been experimenting on the use of unripe tomato seed, and far this is an advantage in causing the plants to pro their fruits earlier and in making them more produc The author arrives at the following conclusions :—

Immature Seed.—The principal deviations arising the use of immature seed are :—(1) A loss of vigour, sh in the smaller percentage of germination, weakness of seedlings, and greater number of plants that die be maturity; (2) failure to recover lost vigour, although plants may, and usually do, produce an abundant harv and one acceptable to the cultivator; (3) the increase o productive parts in proportion to the vegetative pa resulting in a greater number of fruits (seeds altho individually smaller) and the more rapid ripening tha similar plants from mature seeds.

Size of Seeds.—A decrease in nutrition of an organ favours the development of the reproductive parts at expense of the vegetative parts. The decrease in nutri may be brought about by poor soil, bad tillage, germination, &c., all leading to the same general re But it was pointed out that while partly starved pl are, as a rule, proportionately more productive, *i.e.*, per of vegetative part, the reverse is true of plants gr from large and small seeds, for "large seeds pro stronger plants with a greater capacity for reproduc than small seeds of the same kind." These conclusi which are supported by experimental data, stro emphasise the necessity of using only the largest s (that is, screening out and discarding the small seeds) sowing, in order to secure not only the largest yield of g and fruit, but also to retain the vigour and permanency the race under high tillage.

The Exchange tax on tea.

The loss that ensues by mean an artificial exchange to the Ind and Ceylon tea-industry alone, reckoning the great coffee or indigo industries, may be down roughly at the enormous sum of *two million pou sterling*. Sir James Westland is said to boast of hav "saved" the rupee from a fall to the exchange value fine saving truly, that enforces such prodigious loss on country at large. Mr. McEwan, in a forcible letter to *Home and Colonial Mail*, puts the matter clearly enough all to understand: "The total imports of Indian Ceylon teas into the United Kingdom during the calen year of 1897 were 228,000,000 lb., and the average p realised for same in London public auctions was roug $8\frac{1}{2}d$. per pound. It is improbable that, taken over all, profit on production exceeded $2d$. per lb., and allow another penny per pound for freight and charges not s ject to exchange, we get $5\frac{1}{2}d$ per lb. as the average l cost of production at the ports of shipment—Calcutta Colombo. This cost has to be remitted in some manne other to India or Ceylon, and on a yield of 228,000,000 we get £5,225,000 as the crop outlay for the year.

"Taking the average rate of exchange for 1897 as 1*s.* 3 and deducting from same the $9d$. admitted by Sir Ja Westland to be the present real value of the rupee, we h $6\frac{1}{4}d$. per rupee loss, or an aggregate loss during the yea £2,190,000 to the tea industry from exchange alo Roughly speaking, therefore, every penny up or down exchange quotations means £340,000 less or more in revenue from British-grown tea. The calculations have

worked out to a nicety because the complete data for king them do not exist, but the result shown cannot ar from an actual one. The amount of capital invested ea estates in India and Ceylon is somewhere near 000,000, and it will be apparent that those who hold investments are being taxed to maintain a high rate of hange to the extent of something like 5 per cent. per um on the capital value of their holdings."

coffee market.

New crop arrivals continue to come forward so slowly, says the *M. Review* of 22nd ult., that supplies are on a very ted scale, and the auctions have consisted mainly of esirable qualities, at least so far as the home trade is cerned. Larger quantities of Jamaica have been offered, they were principally of ordinary quality, which could be disposed of slowly at rather cheaper rates; the few of medium fetched steady prices. Only small parcels of sta Rica have again been offered, and prices have been l maintained; the finer lots realised rates quite equal to year, while one mark of extra fine sold at a higher e than has been recorded for some years. With a fur- slight fall in the lower grades of coffee this makes a er range of values than has ever before been known. other kinds coloury Colombian has again shown a slight ance, but compared with Costa Rica this kind is still tively cheap. In the terminal market not much has n done, but receipts having continued on a heavy scale, tations have given way about 9*d.* per cwt. The Dutch ding Company have advertised their next sale for Tues- , when 30,300 bags and 30 cases will be offered, against 850 bags and 165 cases at the corresponding sale year.

LETTERS TO THE EDITOR.

HOUSEHOLD QUERIES.

SIR,—I have two questions for "Planter's Wife," and hope she may be able to answer them early:—

I. Recipe for pine-apple liqueur.

II. Can butter be made out of goat's milk and, if so, how?

Yours,

BACHELOR.

SULPHATE OF IRON.

DEAR SIR,—I sent you to-day a paper on "Plant roots as tillers of the soil," which has attracted much notice in England, as it contains certain principles which may be of interest and service to some of your readers.

Permit me to ask if any of your readers have had any experience of the use of Sulphate of Iron? I have been making some small experiments with it here, and it certainly seems to improve the wood and darken and thicken the leaves of the coffee-trees. I have tried it in Scotland for the turnip crop, but with no result.

Faithfully yours,
ROBERT H. ELLIOT.

[The pamphlet received with thanks; it will be duly noticed in a future issue.—ED.]

MR. QUARME AND HIS LEAF DISEASE CURE.

SIR,—So Mr. E. A. Quarme wishes me to apologise for what he thinks an undeniable reference to his "cure." I apologise willingly, and state gladly that "you are *not* ready, some of you, to try, &c."

It is, indeed, perfectly clear that Mr. Quarme cannot be classed among those long out of touch with latter-day planting conditions, for does he not state, or lead one to infer, that he was a coffee-planter up to such a short time ago as 1880, a paltry 17 years? It is also extremely interesting to note that Mr. T. J. Ferguson and the late Mr. Gordon were shown the "cure," with the result that he was advised to take to Metallurgy.

Of course I have no interest in decrying Mr. Quarme's alleged cure, but if he wishes for success, he will, I hope, submit more conclusive evidences to the value of his discovery than a reference to a bumper crop in the seventies. For bumper crops are occasionally got nowadays, he will be surprised to hear.

It is a pity, on my side of the question, that Mr. Quarme should be ignorant of the change in coffee cultivation since 1880; it proves so conclusively that he has kept himself in intimate touch with South India.

I am, Sir,
THE OFFENDING CORRESPONDENT.

TERRACING *vs.* DRAINS.

SIR,—The letters by "W.P." and "Nemo," in your issue of the 5th instant, were instructive and interesting. I see "Nemo," writing from Kadur, asserts that no ill-effects need be feared by desiccation of the soil resulting from terraces. In fact, if anything, he states that it would do good by promoting heavy wintering. This is all very well, but surely in his experience he must have had experience of spike being burnt off by drought; of young crop dropping off for want of sufficient moisture; and finally of crop refusing to ripen properly, and primaries dying back from the same cause. This being a very important question, I hope he will examine it a little more

Advertisers are notified to send all advertisement matter and answers to advertisements direct to Manager, this paper, 3, Esplanade Row, Madras

Correspondence and matter for publication to be sent to Editor, this paper, Coonoor.

carefully, and give a revised answer. I quite admit that a heavy wintering is necessary, mind.

About the width of terraces, I am conscious of having failed to notice an important point, which in fact we have all three omitted to take into account. I refer to the space occupied by the natural fall of the excavated soil. For if no stone is available to build retaining walls with, the loss of area must be considerable. Suppose the fall of the land is as great as one in one—and "H. W. P." must remember that such land is often planted up very successfully in some parts of South India—let us see how terracing would work. The natural angle of excavated earth depends of course on its nature; with a loose soil such as is usually found on steep land, the angle, as far as I have been able to judge from casual instances, is no more than one in one. If this be so, it is evident that in making terraces four feet wide, you must cut quite four feet into the solid. In other words, the excavated soil will occupy the same, if not more, space than before it was cut This can, I think, be made clear with a pencil and paper, so that the *whole* of his terrace will be of loose earth. What says "H. W. P." to this? I have read his letter through carefully and cannot find any reference to this point. The area lost for planting is thus the width of the terrace itself. So that planting a single row of trees in every four-foot terrace, they would actually stand eight feet part, which would be absurd. It is possible, though, to have narrower terraces, I think with tea. Coffee would be planted all right in four-foot terraces, if no danger were feared from drought. Tea *might* be worked on three-foot terraces. In both cases the full width of the terrace would have to be cut in the solid, assuming 1, that stone is not used; 2, that the fall of excavated earth is 1 in 1; 3, that the fall of the land itself is 1 in 1. An acre would contain only 35 of 3 ft. terraces, each say 70 yds. long. Reckon this at 35 rupees, or 70 running yds per rupee. Of four-foot terraces an acre would contain 26. At 50 yards per rupee this runs out to about the same. But then an acre of tea 4×6 on three-foot terraces would stand at 4×6 and would only contain 1,814 plants, instead of the usual 2,722 if at 4×4. Coffee on four-foot terraces would really stand at 5×8, or at 1,089 per acre instead of 1,742 if 5×5.

The less the slope of the land, of course the less the loss of area in terracing, but as the steepest lands need terracing most, it is important to note its results first. With stone work available, we could get just double the number of terraces, the cost of which, being half as broad only in the cutting, would remain the same per acre. The cost of the stonework would be, roughly speaking, about 50% more, against which must be set the gaining of the area otherwise lost.

With land of a fall of 1 in 2, the loss of area would be less, even without stone walls. The cost of cutting terraces again would be much diminished.

As I may have gone wrong in my calculations, I should really be obliged by "H. W. P." correcting them.

To the concluding part of his letter, though, I must take exception. Surely it is easy to understand that clearing silt from drains is far easier work than cutting into even surface soil, which is full of matted root and stumps? If he would take my advice and consult his Peermaad friends (whom "Nemo" seems to think are not located in South India! as to the relative cost of the different estate works, he would learn a lot. And having learnt it, he would be able to give us really valuable hints. His assertion that wash cannot be stopped by interlinear drains or trenches is one which he should try to explain. With his terraces, half of which, even according to his own showing, are loose earth, he has the rainfall on each terrace *plus* the flow from above, which on a ten-inch night must be enormous. With drains or trenches every row of plants, I have a fall surface, sloping it is true, of four to six feet only, accordi the distance apart of the trees. Can there be any appre wash in that distance? Besides, what wash there is, is ca in the drain, if of a good gradient.

In conclusion, I would ask "Nemo" to detail his syst drainage, which he asserts cannot prevent wash on steep as my experience of drains is just the opposite. By the I may as well change my *nom-de-plume*, as I think that "1 is not so apt a term in my case as "1 in

GENERAL ARTICLES.

PLANTING IN JAVA AND CEYLON.

INTERVIEW WITH MR. FRANK ADAM.

As our readers, says the *Ceylon Observer*, are aware, one o visitors to Ceylon at present is Mr. Frank Adam, who is very la interested in coffee planting in Java. Mr. Adam came here i beginning of December last, and since then he has been trave about the Kelani Valley, Kandapola, and Uva districts. His will extend till the end of February, and during that time he w some more visiting in the hill and low country. He was the fi interest Ceylon capitalists in coffee planting in Java—men su Messrs. G. A. Talbot, H. J. Starey, D. & J. R. Fairweather, W Wood, Rutherford, Reid, &c., and the Glen Nevis Company, st in 1892-93, is doing so well that those interested are, along Mr. Adam, now engaged in taking steps to float a Company he start a further block of similar land in the same district of Ja the Glen Nevis Company. That and the extension of this Nevis Company, he explained to an *Observer* representative interviewed him to-day, was the object of his visit to Ceylon.

SIGHING FOR THE COFFEE DAYS.

Asked about his impressions of Uva, he said:—I have met a many old coffee planters, and one and all of them sigh for the c days again in preference to those of tea. With regard to coffee I speak with a certain amount of reserve, because the situation o island, the soil, and the climate are entirely different from Java my impression from what I have seen, and from what I have h from old planters, is that one cause for the decadence of coffee is that the plant was forced and grown under unnatural c tions; that under those same conditions the tree in the magnif volcanic and humus soil of Java would have a chance of a longe and a chance, with proper remedies, of recovering itself. From I have seen, the soil here is not altogether what coffee loves, b I have said I speak with some reserve. When I say that coffe been forced here, I mean that it has been grown without shade. Java we grow the coffee entirely under shade. In the second until I came here, I never understood the meaning of what Ce men said when they talked of pruning and handling coffee. Th me is another means of forcing the tree, and thereby taking as m as possible out of it; and while it gave good crops as long lasted, that rendered the trees less able to withstand any ou attacks. Our

METHOD OF CULTIVATION IN JAVA

is to have no topping at all on high elevations, while on l elevations we top from 5 to 6 feet, leaving a flat surface on the u portion of the tree, and we do not go in for such an unna process as pruning and handling. That is in contrast with wh have seen in Uva, where they top the tree at about 2½ feet and l the head of it exposed to the full force of the sun and the Another thing I notice is that the coffee, or what remains of coffee, is growing in some places on slopes amongst boulders stones. Uva planters seem to fancy that the worst spots for gro coffee are in the sheltered places at the foot of slopes. In such steep slopes abounding in boulders and stones would be lo upon as unplantable, and some of our best coffee in Java is grow the very spots at the foot of slopes, which Ceylon planters, as fa I am able to judge, seem to condemn.

THE SOIL.

Then in Java, the soil, especially where we are, is composed

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

the most part, of deep vegetable humus mixed with volcanic ash. Going through the jungle, one is able in most places to put a common walking stick up to the head into the ground without resistance. Whereas it seems to me in Ceylon a good deal of the fertility of tea is owing to the climate, we in Java, in addition to our having a good climate, have an advantage in the superiority of our soil.

What Coffee can do in Java.

I will give you an instance of what coffee can do in Java. The Pioneer Company—that is the Glen Nevis Company—started by Ceylon people was first cleared or planted in 1892-93, and the last clearing was completed in 1894-95. At the end of 1897 over a cleared area of about 615 acres under coffee there was produced a crop of the gross value of £220,000 sterling. The amount yielded to the end of 1897 from the first year's clearing (1892-93) showed the equivalent of production of 15 cwt. of coffee per acre. At the end of the third year the land produced on the first year's clearing 5 cwt. an acre; at the end of the fourth year 7½ cwt. an acre; and at the end of the fith year (1897) it produced the equivalent of 15 cwt. an acre. The proprietors are so well pleased with the results that they are putting all the profits into further clearing, the estate having a large jungle reserve. As regards

The Rainfall

it is very well distributed, not one month being without a certain proportion of rain. The heaviest rainfall is from October to March inclusive, and the average annual rainfall is from 85 to 87 inches. As regards

The Temperature

the observations taken at six o'clock in the morning, mid-day, and 8 P.M., in the verandah of the Superintendent's bungalow showed a range at 6 A.M. of not lower than 67 and not higher than 72 Fah.; at mid-day not lower than 75 and not higher than 84; and at 8 P.M. not lower than 72 and not higher than 78.

Concessions by Government

are not granted to the outside public, but only to Dutch subjects and foreign subjects resident in Netherlands India. The lands acquired by the Ceylon planters were, therefore, obtained through myself as a resident, having had 23 years' experience of Java. The conditions upon which the Government give the land are very fair, but they are very slow in making grants. They alienate no land. The land is given out by the Government on a 75 years' lease, and if nothing is said to the contrary at the end of the lease, it is renewable, so that it is practically ownership that one receives. The Dutch law allows the mortgage of these lands in the same way as freehold property, subject of course to the conditions of the occasion. No tax of any kind is payable until the end of the fifth year, when an amount is levied, which varies, but which may be put down at a maximum of one Java guilder (equal to 1*s.* 8*d.*) per bouw, which is equal to 1¾ acres. No obligation is imposed as to bringing the land under cultivation. In British Colonies you are obliged in most cases to undertake to bring so much under cultivation within a certain time, but in Java there is no such stipulation. As regards other taxes there is no tax levied, until the estate comes into profitable bearing, when the usual income tax is levied, which is somewhere about 2 per cent. The Government reserve to themselves all rights to minerals on the lands, and also the rights to open roads and water-courses, subject to compensation being paid to the concessionaires. They will not permit the manufacture on the land of salt, which is a Government monopoly, or the cultivation of the poppy for opium, which is also a Government monopoly.

Report by a Ceylon man.

A well-known Ceylon man, who is also interested in coffee in the Straits—I refer to Mr. Donald Mackay—was down in Java, and after seeing the lands reported most favourably on them. With regard to Glen Nevis, he said that the soil, situation, and growth of the clearings were far beyond that of any plantations he had seen in many of the countries with which he was acquainted, and the reality was better by far than the descriptions of his Ceylon friends had led him to expect. The sheltered situation, encircled on all sides by mountain ranges, the uniform richness and depth of the dark volcanic soil, and the luxurious growth of trees from two and-a-half to four and-a-half years' old could hardly be excelled, if it could be equalled, by Arabian coffee in any part of the world. The Liberian coffee trees had made fine progress. As regarded the cacao trees, he was inclined to think from their appearance that they might do better next year (1898) than progress had led planters hitherto to expect. So far as his information went, the climate of the district generally was comparatively healthy; there did not appear to be much malaria; and the outbreaks of cholera which had been recorded were due more to preventible causes, such as carelessness of the coolies themselves, than any unhealthiness arising from situation, soil, or climate, or water. Continuing, Mr. Adam said :—The total acreage planted on Glen Nevis and the neighbouring estate by the same proprietors up to the end of 1897 was about 1,400 acres, of which two-thirds are in bearing. Off this acreage the gross value of the crop for 1895, 1896, and 1897 was £35,000 sterling.

Arabica and Liberian Coffee.

Our experience is that we obtain much more favourable results from Coffee Arabica than Liberian coffee. Liberian coffee has been planted in these concessions experimentally, but our attention is devoted to Arabica. Liberian coffee experimentally is doing very well, but the Arabian is what we depend upon. We argue that as long as we can find good land to grow Arabica, it is better to grow that variety. As a fancy coffee it has very few competitors and we think it much better to leave alone Liberian which may be classed among the coffee of the many and not of the few. The wisdom of our doing so is evident from the fact that during the recent crop in coffee, such rough varieties as those of Brazil, Santos, Liberia, &c., experienced a very heavy fall, while the fall in fancy coffee, such as Java, Ceylon Plantation, Guatemala, was not appreciable. In fact, since I came to Ceylon, I have seen a quotation of bold, coloury, yellow Liberian in London at 44s. per cwt., while Ceylon Plantation, which is very much the same preparation and quality as Java private estate coffee, was quoted in the same market report at 100s. to 102s. Comment upon that I think is needless.

Geography.

Java, for agricultural purposes, is practically divided into two portions. The Western portion, which is nearest Batavia and the main lines of sea communication, is the part which is mostly seen by the globe-trotter. The climate of this part is very humid, and the soil, upon which tea in the uplands is principally grown, is stiff and red. The east end of the island, which very few people take the time to run down and see, and which is remote from the main steamer lines, is the Garden of Coffee in Java. There is direct railway communication from Batavia to Djember quite close to the extreme east, and the line has been surveyed for a further extension from Djember (tunnelling through a mountain range) to Bangœwangte, one of the principal stations of the Eastern Telegraph Company and the most easterly port in Java. It is from that port that the Glen Nevis coffee is shipped, the distance between the estate and the port being 38 miles, 25 of which are over a good Government post road and the balance over a good riding track. As regards

The Population

it consists in the first place of Sundanese (Aborigines) inhabiting the west or tea districts of the island. They are less hardy than the inhabitants of the east end of the island, who are composed of Javanese (also indigenous) and Madurese, who crossed over to Java from the island of Madura immediately adjoining. There are also Malays in Java on the western sea coast, the descendants of Malay pirates in days gone by. These people are not employed as labourers, but as household servants, coachmen, &c. The total of the population is about 23½ millions. The labour supply is very good. We have our own labour difficulties, like the planters in every other part of the East, but these have been reduced to a minimum. When Sir Stamford Raffles was in Java in 1810 to 1812 the population was somewhere about six millions, and the figures now show how the natives have increased and multiplied under the Dutch rule. In regard to

The working of the estates

we find it better to have that done by Dutchmen and according to Dutch methods with an Englishman at the head of the whole affair. The system works better than employing Englishmen who are not acquainted with Dutch methods, customs and language. The wages of a cooly on a coffee estate average about 40 to 45 guilder cents per day.

Exchange

is on a bi-metallic basis, and therefore we do not have the fluctuations to which silver countries in the East are subjected.

THE ROADS

are amongst the finest in the world, and for the most part beautifully shaded on both sides with tamarind trees.

OTHER PRODUCTS.

The land grows sugar very well indeed; but owing to the continental bounties during the last few years, and the change in the tariff duties of America, that industry is in a very precarious state. Indigo grows very well in mid-Java on a limited area. I may mention that at an agricultural exhibition in Calcutta some seven or eight years ago, I remember to have seen that five prizes were given for indigo. The first, second and third fell to Java and the third and fifth to India. Java also produces tobacco, which is grown on a limited area naturally on account of the humid climate which it, like tea, requires. It also grows tea, as I have indicated, also cacao, vanilla, nutmegs, cinchona, &c. In the west of Java there is some of the finest table rice in the world, and throughout the whole island there is the ordinary native rice. Of late years petroleum has been discovered, principally in mid and east Java, and some of the Companies have obtained splendid results.

IN CASE OF FIRE.

YOUR house takes fire. What burns first? The lightest and most inflammable stuff, of course—furniture, doors, shelves, floors, panelling, and other woodwork. If it is a stone or brick house, the walls will probably remain standing—a melancholy sight.

Were not this a principle of universal application, Mr. Meddings would never have compared himself to a skeleton, as he does in the letter to which your attention is now invited.

"In the autumn of 1891," he says, "I fell into a low, weak state of health. My ordinary energy appeared to have gone out of me. I always felt tired and languid, and couldn't account for it. Nothing seemed to rest me. I was as tired in the morning as when I went to bed. I had a bad taste in the mouth, my appetite was poor, and after meals I had a pain at my chest and left side.

"I was in this condition until the 14th of March, 1892, and then I had to give up work. The reason was, I was too weak to work. In fact, I was so weak that it was about as much as I could do to walk across the floor. Besides this I had a dry, hacking cough; and at night I sweat so the bedclothes were wet. Sometimes during the day cold, clammy sweats would break out all over me.

"I lost flesh rapidly, until I was like a skeleton. My muscles seemed to be shrunken and withered. There was no feeling of warmth in me; it was as though my blood had gone cool and thin. I was too feeble and helpless to wash or dress myself, and people said I was wasting away, as though they expected to see the end of it presently.

"I consulted two doctors and they gave me medicine, but it did me no good. One day my aunt, Mrs. Benton, of Francis Street, Walsall, called, and in the course of talk she said that the medicine that did her good when she was ill was Mother Seigel's Curative Syrup. Although it didn't look reasonable to believe that it could cure a case as bad as mine, nevertheless my wife got me a bottle from Mr. Grove, the chemist in Park Street, and I commenced taking it. In a few days I found myself much better; my appetite was better, and I had gained a little strength.

"To make the story short, I kept on taking the Syrup and continued to get better. As soon as I could digest my food the night sweats and the cough abated, and in a few weeks I was able to go back to my work. That is two years ago, and since then I have been in good health, for which I have to thank Mother Seigel's Syrup. (Signed) Arthur Thomas Meddings, 115, Farringdon Street, Walsall, March 6th, 1894."

In a fire, as we said, it is the light, inflammable stuff that burns first. That's why Mr. Meddings got to be so ghastly thin. The flesh or fat is the fuel of the body. In health it keeps up the warmth and furnishes the power. And to keep up the fuel we must eat.

Now, disease is a conflagration; it tries to burn the house up, and often does it. And it always burns the flesh up, more or less of it. The fat goes first, the muscles, &c., afterwards. That's the way of it. About that time *the tenant moves out.*

Our friend was well on towards that point. But it wasn't lung disease that ailed him, albeit he had the cough and the sweats. They go also with indigestion and dyspepsia—his real and only malady. He got feeble and thin because his disease wouldn't allow the stomach to digest food. Hence he consumed all the flesh he had stored up, and then (luckily for him) he began to take Mother Seigel's Curative Syrup, which set his stomach and liver right, and gave his victuals a chance to feed him.

All the same, it is dangerous to let a fire get headway. When it is in your body, quench the first spark with Mother Seigel's Curative Syrup.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (January 28, 1898) says:—The moderate supplies catalogued this week met a fair demand and were mostly sold at previous rates for ordinary qualities, but the bidding for the colory grades was very keen.

Barely 700 bags East India were offered consisting chiefly of the first shipments of Coorg; bold colory parcels realised very full values, the remainder selling at unchanged prices.

Central American kinds show little change for medium description but fine blue Costa Rica attracted keen competition and was easily disposed of at full rates.

A quiet tone has prevailed in the Terme market and fluctuations have been unimportant, quotations at the close being 3d lower than our last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending January 26th, 1898, says:—Bank rate 3%. Bombay Exchange closes at 1s. 3⅞d. Brazil Exchange 6⅞d. Rupee paper 3½% 63⅛. Silver 26 3/16d. per oz.

The spot market has been rather steadier throughout the past week although very quiet, the demand for new crop East India and Costa Rica being very good, and extreme prices being paid for fine. The quality of new crop Coorg and Mysore is, so far, unsatisfactory. Brazil markets are flat and lower. Daily receipts averaged 9,800 bags in Rio, and 10,300 bags in Santos.

At the Dutch sale held yesterday in Amsterdam 32,312 bags and 33 cases were offered and sold at an irregular decline of 2 to 4½ cents except for fine, which sold dearer. Good ordinary Java sold at 34 cents against 35½ cents at the previous sale in November last.

Futures have ruled weak and close 1s. 3d. to 1s. 6d. per cwt. lower, viz.:—Good average Santos in Havre, March delivery, fcs. 36.25, in Hamburg pf. 29¾, and No. 7 low ordinary Rio in New York $5.60.

To-day's London official quotations are:—

	Jan.	March	May	July	Sept.	Dec., '98.

Indian. The market experienced considerable relief through the ter auctions held this week, only 45,006 packages being brought ward. The strain placed upon it by the offering of 121,776 packages fortnight, naturally caused irregularity in prices with a somewhat ier tone. There has been sufficient elasticity in the market to recover m the slight depression, in response to the reduced supply, while the sent very low rates are inducing buyers to operate with more fidence, now that so much of the recent accumulation has passed ough the auctions.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c. Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 4th March, 1898.

Season Reports should be sent to the Printers, Messrs. Addison & Co., direct, and not to *Planting Opinion* Office.

S. E. Wynaad.

Devala, 23*rd February*.—*Weather.*—Since the 20th instant it is very cloudy in the morning and evening, and during the day very windy. *Crops.*—The recent rain brought the spikes forward, which are lingering for rain.—*Health.*—Fair. *Labour.*—Sufficient.

Coorg.

Polli Betta, 23*rd February*.—*Weather.*—Fine and clear with blazing sun and east wind at times. Not much dew. Just about what the weather should be at this time. *Crops.*—Gleaning still in hand. Spike for next season fine and healthy. Will hold out for a good time yet. Coffee seems to have wintered heavily and is looking dryish in parts, but will probably crop all the better for this. *General Health.*—Fever, coughs, colds and dysentery prevalent, but not to such an extent as previously. *Interesting Item.*—Rifle meeting begins 1st March.

Nellampatty (British).

23*rd Feb.*—*Weather.*—Every morning for the last fortnight it has been very cloudy, and on the 15th rain fell all over the district. Some places got over an inch, I hear, but I had only 35 cents here. Land wind has started again this morning and may "blow away" the rain, which seems very near. In a great many cases the last rain has brought on three-fourths of the spike, and several places expect to have the blossom out this week, while one or two have already had a blossom. Prospects are not so good as they would have been had rain held off for another ten days, but still there is not much cause for tall "cussing" yet, and with any luck we may do well. *General Health.*—Fair. Shower brought fever as usual. *Labour.*—Places that had not before paid off, are doing so this week and the district is very empty.

Kotagiri. NILGIRIS, 24*th February.*—Nice blow of flower out, very good on many estates, notably Kil Kotagiri side; it worked up for rain again, but fortunately it has kept off since last report, and by the end of this week blossom should be set and safe everywhere this side.

THE AMERICAN COFFEE CROP.

DESPITE the almost unique qualities of East Indian plantation coffee, the enormous crops of South America during the last two years are having an undoubtedly depressing influence on the market for all grades, even for the finest. There seem no grounds for supposing that the pressure on consumption will cease, for the great and successive increase of the American crop is due to young plantations coming into bearing, and not to a succession of extraordinarily fortunate seasons, as has been erroneously supposed in some quarters.

The world's demand is now far less than its supply, and as a consequence prices have fallen, for American coffee, as low as, if not lower than, they have ever been. A low range of prices must inevitably increase consumption, but the immediate future is not rosy.

The well-known New York brokers, Messrs. W. H. Crossman and Bro., in a circular issued at the close of last year, have some interesting and weighty remarks on the situation. In comparing the present market with the almost equally low one of 1884, they state the Brazilian price averaged 23 milreis from 1884 to 1886:—

"The planter now gets in excess of 48 milreis per bag, and it will require some time before production at this rate becomes unprofitable. The milreis, at the exchange rate to-day of 7 pence, serves just the same purpose to the Brazilian planter as it did at 27 pence exchange, for the payment of interest on mortgages, debts contracted in Brazil, etc. The railroad freight for coffee to the seaports, while much higher than before, is still payable in milreis, and has not advanced in proportion to the low exchange. The cost of labour, which, relatively, should have quadrupled with the depreciation in the currency exchange rates, has only doubled, and it requires a lower price in milreis before planters will stop harvesting what is grown.

"We are informed that the average cost of production in Rio is about nine milreis per arroba, which is 37 milreis per bag of 60 kilos. The average price for coffee, which in quality is better than Rio No. 7, to-day is over 50 milreis per bag, and it is generally admitted that in Santos the cost of production is on a lower scale than in Rio.

"Apart from Rio and Santos, production of coffee in other parts of the world continues to increase, but not so rapidly. Victoria and Bahia are probably producing treble the quantity they did six years ago. The production in mild coffee countries is increasing slowly, but surely. We figure that the arrivals of mild coffees from 1st July to 1st December, 1897, in the world, exclusive of Rio and Santos kinds, are 1,387,979 bags, compared with the same period in 1896, 1,269,796 bags. Reports sent to us from Venezuela are favourable for a larger crop than last year. Costa Rica sends about the same sort of report. Salvador will give at least fifty per cent. more than last year, including what was left over of the previous crop. Guatemala will give probably less. Mexico, the reports are contradictory, but the average information points to a yield about the same as last year. Java, the present crop is estimated at about 400,000 Government Java, against last year 265,000 piculs.

"But the detailed reports from all of these countries are usually colored and unreliable, until the merchandise is shipped down to the seaports, but it is safe to count upon a slow yet steady increase. Speaking generally, we think that, including Victoria, Bahia and Ceara, it is fairly safe to calculate a total of 5,500,000 bags for the current season. The idea that the entire coffee crops will not be gathered in consequence of the price is one that we discredit *in toto*. For many years past we have pointed out the fact that coffee culture gave a profit of from 100 per cent. to 200 per cent. according to the different countries. Even if this should shrink down to the act cost, planters will be obliged to gather the crops which provide th only revenue and means for paying for their necessities. With exception of the high-priced plantations, bought on speculat during the higher range of values, we believe that in all produc countries coffee is still being grown at a fair profit—in Brazil pro bly from 25 per cent. to 33 per cent., and the larger quantities t now gather compensate for the lower price they sell at."

Viewing the Coffee market as a whole, in face of largest visible, invisible and prospective supplies the wo has ever seen, we are forced to the conclusion that we in an era of over-production. The end, moreover, is yet.

With reference to plantation coffee, it is only too lik that a steady, though moderate fall, will take place in except the finest grades. To improve their grade of cof in methods alluded to elsewhere, is a point, therefore, t needs the most urgent attentions planters can bestow.

NOTES.

"The Volunteer." We have received a copy of t new Calcutta journal, which, as name implies, is devoted to the interests of volunteering India. It promises to be a readable journal enough, a Volunteers will probably find their Rs.5-12—its tiny yea subscription—well spent.

Duars planting method. The Duars, as some of our re ers may not know, is a huge t district bordering on Assam, famous for its huge yie and huger plantations. The methods of planting a working generally would form an interesting chapter planting in excelsis. Some of the nurseries contain many as two to three hundred maunds of seed in the ye sufficient to plant up one to two thousand acres. To wa these, steam pumps are used for economy's sake.

Borneo plantations. In a review on agricultural ent prize in North Borneo for the p year, we note that tobacco prices have been quite up expectation. Coffee planters are not happy, as the vari grown is chiefly Liberian, which has fallen in price direct sympathy with the market for Americans. Gamb the "new" tanning product, is doing well and still ma tains its price. Cocoanut cultivation is growing in fav while hemp, rhea and pepper are also being planted

The new style of planting. Some months ago we drew attention of our readers to strong opinion held by Profes Wallace on the inadvisability of planting fruit-trees holes or pits. It has since come to our notice that one the most successful and scientific planters of South In has, within the last few years, given up hole-planting t large extent. In lieu of pits, he has the whole land over at a cost, for coffee, of under double the usual pitt rates, while for tea it is actually cheaper. An Ameri authority on orange culture says: "I have found few pla where fruit trees can be planted with any hope of succ in holes. In a clay soil or clay subsoil planting in ho will be as bad as planting in an iron pot, and I have doubt that the dying back of comparatively young trees the yellowing of leaves must be attributed to that

system of digging a hole in the soil as hard as a sheet, planting the tree and filling the hole with water. The ground should be prepared by ploughing and subsoiling as deep as possible—say 18 to 24 inches—during the rains, and the clods broken up and the land levelled before planting."

Tea market.

Indians.—With reduced supplies and a fairly active demand, writes the *P. M. Review* of 29th ult., the market has been stronger for the medium and lower kinds, with a distinctly firmer tendency for the better grades. As the public sales will probably be on a smaller scale than during the past few weeks, prices may further strengthen a little later on. The large assortment of useful priced tea now on offer at moderate values has stimulated purchases on a considerable scale, and the trade are undoubtedly pursuing a safe course in buying ahead of their immediate requirements. It is rarely that Indian teas can be obtained on such favourable terms by the retailer as is now the case, and this should materially stimulate the consumption, especially as exceptional value for the more popular canister can be supplied to the consumer. There are already indications of the season coming to a close, as some final invoices have already been catalogued, and from recent advices it appears that the total yield will not materially exceed that of last season. The quantity brought forward at the public sales comprised 45,126 packages against 62,649 in the preceding week, and 6,082 were withdrawn. The bidding throughout was active for all good descriptions, more particularly Assam growths, those taken out of sale being poor liquoring sorts of Calcutta purchase.

Light Railways for the Colonies.

In the paper which he read on the 1st inst. at the Royal Colonial Institute on "Light Railways for the Colonies," Mr. Everard R. Calthrop, C.E., gave reasons in support of his opinion that cheap and narrow gauge railways are best adapted for opening up territory in the shortest time and at the least possible cost, while possessing at the same time a large carrying capacity. Without overloading his matter with figures, he set forth calculations, based on practical experience, which distinctly made in favour of light railways. As an example, he referred to the Barsi Light Railway in India, in the construction of which he followed out the principle that the substantiality of permanent-way depends solely on the weight per yard of rail having a proper relation to the maximum weight per axle of the rolling stock to be placed on it. The Barsi Light Railway—the cost of building which, including rolling stock, was about £3,000 per mile, the work being all of a substantial and permanent character—was only opened for traffic in March last; but during its first half-year of working the operating expenses in India were just below 50 per cent. of the gross receipts, and the net profits earned were in excess of 4 per cent. on the capital of the company, notwithstanding an almost unexampled combination of troubles, including plague, cholera, and famine with their ruinous effects upon traffic.

Cheap nitrogen.

We can always find room for paragraphs on our nitrogen supply. When it is reckoned that, if leguminous trees were grown in or amongst our tea or coffee, we should gain quite a hundred rupees of nitrogen per acre—well it seems worth considering. Says a Ceylon exchange:—"Numerous experiments and investigations, including the cultivation of crops under careful observation by practical men, have resulted in general belief and acceptance of the following facts which may be turned to practical account: (1) that leguminous plants well furnished with root nodules will collect and store per acre the nitrogen supplied by several hundred pounds of guano, nitrate of soda or sulphate ammonia; (2) that when the spores of the bacteria are distributed in the soil and taken up by the root hairs of the plants, these spores induce abnormal growth in the tissues of the roots and increase to many millions of organisms in a short while; (3) a soil may contain some of the bacterial spores and therefore there may be no nodules formed. And as each variety of leguminous plant appears to be the host of a special bacterium, it is quite possible that the one required may not be present to invest and form nodules on the crop; so that in both cases there would be no nodules or collection of nitrogen. To provide the proper bacteria in the soil, a mode of soil inoculation has been adopted. A small quantity of soil from a field in which a good crop of the special legume to be cultivated has been grown is spread over the new land."

Nitragin experiments.

In detailing the results of the experimental work at the Woburn Experimental Farm, Dr. Voelcker writes as follows:—"The new inoculating material, 'Nitragin,' as is now known, was intented to promote the growth of leguminous crops by enabling them to form the nodules on their rootlets which are so closely associated with the assimilation of nitrogen from atmospheric sources. It was, therefore, only natural that an extended series of experiments should be carried out with it at Woburn, and chiefly in the hope that it might prove a solution of the 'clover-sickness' difficulty. The experiments must, however, be for the present dismissed with the remark that though here and there there have seemed to be some indications of success attending the employment of 'Nitragin,' nothing of a definite nature has been ascertained, and one is rather driven to the conclusion that our ordinary agricultural leguminous crops do not find lacking in the soils of this country the organisms which they require for nodule development and nitrogen assimilation. In experiments carried out with beans, it was noticed that, when the *seed* had been inoculated with the 'Nitragin' proper to it, the crop came into flower at least eight days before there was a sign of flowering in the other plots; that the next plot to come into flower was that the *soil* of which had been inoculated with the 'Nitragin,' and the latest of all was the untreated plot. The early flowering, however, seemed to result in a stunted growth later on."

Large coffee-beans.

With the present trend of the market, it becomes far more important than ever it was before to make the proportion of A or No. 1 grade as large as possible. The prices of the first sizes of plantation coffee are now almost double those of the lowest grades, showing a range of prices indeed that is quite novel to East Indian coffee. Means in plenty to effect the desired end, *i.e.*, to obtain the major portion of

the crop in the higher grades. Some are foolish, others impracticable. Others again are worthy of close attention. Heavy pruning and liberal manuring—the first of which is in striking disfavour compared to the esteem the latter is held in—are recommended with obvious force. To take an extreme case, it pays better to get 10 cwt. of 90*s*. coffee than 15 cwt. of 50*s*. grades. Less again is taken out of the tree by the smaller crop. Heavy pruning doubtless reduces the crop, but each berry on the tree, backed up by liberal manuring, has a far better chance of attaining its fullest development. But, as a correspondent points out, there is something yet more necessary, and that is, the importation of new and better varieties than we possess at present. Were cross-fertilization with Liberian systematically followed according to the lucid directions by the well-known expert "J. C.", the result would speedily show itself in the shape of a large and better bean. A simpler way would be the larger planting up of maragogipe, which bears an extremely larger and handsome bean, delicate though the tree is and much subject to leaf disease. Some few bags of maragogipe were sold on behalf of a Nilgiri planter and realised extreme prices.

Rubber in Ceylon. The fourth circular issued by Mr. Willis, Director of the Ceylon Botanic Gardens, affords a very good and useful summary of information on the subject of "Rubber," although, so far as we, states the *Ceylon Observer*, can see, there is nothing specially new, and a good deal of the practical information is taken from the reports of the Forest Department. Mr. Willis tells us that the world's consumption of rubber is now over 100 million lb. per annum, worth more than 10 million sterling, and nearly half of this comes from Para. We shall be compiling full statistics shortly for our Handbook, and will be able to verify these estimates. The discovery of the new rubber-yielding tree, *Kickxia africana*, has met the increasing demand and kept prices down; but the reckless destruction of trees in collecting must erelong tell. Mr. Willis proceeds to give an account of the Para district, the estimate and soil suited for *Hevea* (the Brazil rubber), the mode of planting, rate of growth, the mode and yield in tapping. He shows that tappings at weekly intervals of trees about 2 ft. mean girth in 1897 gave a return of 5·17 oz. per tree. Heneratgoda experiments point to 90 lb. rubber per acre after 20 years—not very encouraging; but Mr. Willis thinks better results can be got by planting closer and tapping earlier. As to cost of opening plantations, he takes R75 per acre for cost of 300 acres of land and shows a total outlay of R75,777 up to the 10th year, or with interest at 7 per cent. R110,000 equal to R366·66 per acre. Taking the yield in the 10th year of this properly planted plantation at 100 lb. per acre, we get a gross return of £10 or R150 per acre, and taking R50 for cost of harvesting, carriage to London, &c., we get R100 an acre, or 27 per cent. on outlay, leaving an ample margin for contingencies and satisfactory profit.

Coffee market. At the Dutch sale on Tuesday, with the exception of the finer grades, writes the *P. M. Review* of 29th ult., there was a slow demand, and prices for the commoner sorts receded from 3 to 4 cents below the previous sale. Here there has been much the same kind of market, for little business can be done in the lower qualities, and to effect sales a reduct has generally to be accepted, but the finer sorts are scarce that higher prices have again been paid. New c Costa Rica continues to arrive in such small quantities t there has been no chance to fairly test the market, and few lots of moderately fine have fetched rates even hig than those that were ruling last year. Of the new c East India there has again been a decided advance in bold, and though the next size has sold rather dearer, th is still an extraordinary difference between the prices p for the two sizes, in some instances as much as 25*s*. per c a larger variation than was ever before known, and which must lead to more attention being paid to the B than to the bolder. In the terminal market heavy rece and large estimates of the coming crop have caused a of about 6*d*. per cwt., but there is a firmer tone noticea at the close.

Citronella Oil. Citronella oil, about which a co spondent was enquiring lately, extensively used in perfumery and for other purposes chiefly obtained from Ceylon and Singapore. It has b noticed for some time, says an exchange, that the nati distilled oils have an aroma much inferior to those disti by Messrs. Fisher of Singapore and Messrs. Winter Son of Galle, and that these two classes of oils also sh marked differences in physical characters. Messrs. Um and Swinton have lately examined a number of commer samples of both classes, and their results were commu cated to the recent British Pharmaceutical Conference. the case of the native oils, submitted to distillation residue amounting to 37 per cent. of the total was behind, while the whole of the oil from English fo distilled over. This difference was thought to be due the fact that the latter were steam distilled and the la obtained by fire heat. The residue referred to was distil after purification, between 245 and 280c., and had a h specific gravity, possessing all the properties of a sesqui pene, but differing in physical properties for any previou described bodies of that class. Being odourless it is c sidered a valueless constituent, while being fairly solubl affects the solubility of the oil. Again, it was found t while camphene was almost entirely absent from the na oils, the oils of the English firms consisted chiefly camphene, the active terpene of the native oils being abs owing probably to its having been removed. The chemi therefore, conclude that the native-distilled oil is in no sophisticated, but is a genuine natural oil. [It would interesting to know (1) whether the natives use any ot grass other than, or in addition to, the true citronella gr

he cultivated form of *Andropogen nardus*), and (2) whether ny difference as suggested in the above report is the nethods of distillation by natives and Europeans. Some ears ago it was pretty well known that a good deal of dulteration with kerosene oil was practised by the natives. Has this practice been given up now, or have the manufacurers found another adulterant which chemists are unable o identify ?]

The Anaimalais. The Madras Government, says the *Pioneer*, it will be recollected, nade an effort last year to open up the reserve forest land on the Anaimalai Hills on the Travancore frontier; and in April last some 15,000 acres of forest land were put up for auction at an initial bid of Rs. 5 per acre. The land was disposed in blocks, each comprising 1,000 acres as a maximum; and no single purchaser was allowed to acquire more than one block. The reason for imposing this restriction was to prevent the land at the very outset from falling into the hands of a few parties, or perhaps of a single individual; for the object the Madras Government had in view was to try to establish a colony in this region, the members of which would be directly interested in the land. If a number of purchasers could be procured, great progress would be made in the realisation of this plan. Moreover, 350 acres were specially reserved, so as to serve for the locality of a town which would probably spring up in the centre of the projected colony. In addition a road some 25 miles in length is now in course of construction, and extends from the base of the hills up to the estates, which are situated at heights ranging from 3,000 to 4,500 feet above sea level. The land was given up by Government on very easy assessment, which was settled for a period of forty years; but every purchaser had to undertake that he would cultivate his land within six years. The soil is excellent, and it is stated that no manure will be required for ten years, as forest drippings have abundantly covered the soil. When the auction of land took place last April, the advantages of taking up land on the Anaimalais were evidently not realised by the public, for few purchasers came forward and there was practically no competition at the auction. Some well-known firms, among whom were Messrs. Finlay Muir & Co., entered the field, but they, like private purchasers, were limited to the acquisition of a single block. The Madras Government, however, did not provide against the subsequent sale of blocks by purchasers, and it is difficult to see how they could have imposed any prohibitory conditions with regard to such transactions. The consequence has been that wealthy purchasers have bought several blocks from their original buyers, and the latter have made enormous profits over the sales: having disposed of the land at three or four times the price which they paid to Government. In May next it is understood that the Madras Government intend putting up for auction some 80 square miles of forest land: but this time it is expected that the competition will be severer than last year; for speculators are just beginning to get wind of the extremely profitable transactions of some of the purchasers of last year. The region which is being opened up seems to be full of promise; and hopes are entertained that a fairly prosperous settlement will soon spring up here; but doubts are felt as to whether the original intentions of the Madras Government will be carried out. As matters stand at present, it looks as if the capitalist and speculator would exploit the situation between them.

Exchange and planting in Assam. A Calcutta correspondent reports the present stagnation in the late vigorous extensions of tea, owing to the severe and continued rise in exchange. Half a loaf, he urges, is better than no bread, and if exchange is to be high, why, let us hope it will be fixed permanently at one level. This is plausible enough, but we say, if exchange is to be fixed at all, let it be on a low level. The influx of cheap capital induced by a *fixed* exchange, not because it is high, mind, will be doubtless of great benefit to the whole country, planters included. But there is not the least necessity, with the exception of importing traders and Government, of the exchange being fixed at a high standard at all. Our correspondent admits the evil effects of a high exchange on agriculture by referring to the imminent abandonment of many large areas of poorly-planted tea. Cheap capital is good and very welcome, but the profits from a low exchange are a great deal higher than the margin of difference between high and low interest on capital. For as sterling capital used in India means practically rupee capital, a high exchange, joined with cheap sterling capital, simply means that, as the rupee capital is the same, a larger equivalent in sterling will be needed. In tea, a certain saving is made by cheaper machinery, but expenditure on machinery forms by no means a large proportion of the total outlay per acre. In coffee, even this saving is lost. To put it into figures. Suppose that exchange is fixed at par, *i.e.*, Rs.10 to the £1, and that the rate of interest is only 5 per cent. For every thousand rupees borrowed interest must be paid on £100, which at 5 per cent. is £5 or Rs.50. Supposing exchange, however, was as low as Rs.20 to the £1—as it would be now, were the honest rupee still in force—, and interest was as high as 10 per cent. We should still require to borrow only a thousand rupees, *i.e.*, £50, on which the interest at 10% would be £5 or Rs.100. It is clear, therefore, that we are paying double interest on our capital. But let us now take the profit side of the question. We will assume that the net sterling proceeds of our crop are £100, out of which we have to pay Indian charges only. At par, this would realise only one thousand rupees, but at Rs.20 to the sovereign, we should net just double. Assuming, for the sake of argument, that Indian working expenses are Rs.500, the profit at par would be Rs.500, while at the lower rate the profits would be Rs.1,500. The capital required to produce these results

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton:—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

may be put at Rs.7,500, in sterling £750 at par and £375 at 20*s.* per £1. The interest on the former amount at 5% would be £37-10 or Rs. 375; the interest on the latter at 10% would be £37-10 or Rs.750. The interest at par would only leave Rs.125 profit, while at 20*s.* per £1 there would still be the margin of Rs.750.

To conclude our dissertation, the relative profit in rupees at par and at 20*s.* per £1 are as 6½% to 25%.

And to think, if there were any sense in high places, that we could get both low exchange and cheap capital by the simple expedient of fixing the exchange, if fixed it is to be, at a low rate. Of course, the rupee will not be made exchangeable at par, so that in effect the contrasting ratio of interest would be as 10% is to 25%.

LETTERS TO THE EDITOR.

ANSWERS TO CORRESPONDENTS.

["Vale."—You have mixed up "high" and "low" exchange in such a manner that your argument is unintelligible. Try and put your ideas ship-shape and write us again.—ED.]

TO KEEP PASTE SWEET.

SIR,—It may interest some of your readers to know that, by the addition of a few drops of such preservatives as blue-gum oil, oil of cloves, &c., it is perfectly easy to keep home-made paste sweet for any length of time.

PASTE.

HOW E. LITHOSPERMAS GROW.

SIR,—For the last few years we have read a great deal of the wonderful *Erythrina lithosperma*, and there are, I fancy, few planters who cannot show some thousands of this tree on their estates. It would be interesting to know more of the growth of this tree, and at what elevation it thrives best. Last monsoon (July) I put out a few thousand plants *in baskets* which were 1 ft. high; some now are over 8 *feet*, while a good many after eight months' growth are only 2 feet high! Many are full of leaf, but most of my plants are leafless. Is this the same in all districts?

The dry weather is the time when all shade plants, to be of any use, ought to have their leaves on, so where is the advantage if the E. L. drops its leaves in the hot weather?

Some of my plants have thorns on and exactly like plants of *E. indica* (Can. Halwan), which in my humble opinion is just a variety of E. L.

"D."

PRICES OF PARCHMENT COFFEE.

SIR,—It would be interesting to note the prices of parchment coffee in different districts. A leading firm in Calicut offers Rs.11—14 per bushel of parchment delivered at the store on the Shevaroys, with a guarantee of 85 bushels to the ton, while here in Mysore the ruling price is between Rs.9 and 10, and yet Mysore coffee is supposed to be far *superior* than any other.

The outturn in this district this year is considerably over 90 bushels per ton, and yet firms demand a guarantee of 85 bus.

"FOXY COFFEE."

GENERAL ARTICLES.

U. P. A. S. I. SECTION.

RE-OPENING OF THE MINTS.

THE following is a copy of a Circular that has been issued to all Members of the Committee, together with a copy of the Chairman's letter to the Government of I expressing our views on this most important question:

MADRAS, 22*nd February*, 189

CIRCULAR.

TO ALL MEMBERS OF THE COMMITTEE.

DEAR SIR,

I beg to hand you, herewith, a copy of a letter on the cur question addressed by the Chairman to the Government of Ind

You will remember that only a very short time ago the M Chamber of Commerce addressed the same Government on subject, giving its views in favour of the adoption of the Lin Scheme or of some modification of it by which the exchange of the Rupee would be kept fairly stable at 1*s.* 4*d.* The ge trend of opinion would appear to be in this direction, and it necessary, if we were not prepared to have the exchange que settled in a manner antagonistic to our interests as exporters, we should take immediate steps to place our views before Government of India.

The matter having, therefore, become urgent, there was no to be lost, in the Chairman's opinion, in making the autho acquainted with the views of this Association as expressed in Circular letter issued to all Chambers of Commerce, etc., and he has accordingly done in the letter herewith circulated.

A copy of the Chairman's letter was supplied to the Press so full publicity might be given to our views.

I am, dear Sir,
Yours faithfully,
(Signed) ALLAN RONALDSON
Ag. Secy., U. P. A.

FROM

GEORGE ROMILLY,
Chairman, U. P. A. S. I.,

To

THE SECRETARY TO GOVERNMENT OF INDIA,
Financial Department, Calc

SIR,

As we observe that the Madras Chamber of Commerce has rece laid its views on the currency problem before the Governmen India, and as we note with alarm that it advocates the adoptio what is known as the Lindsay Scheme for establishing a standard, and thereby fixing the rupee at about 1*s.* 4*d.*, I now the honour to submit for the consideration of Government the v of this Association on the subject representing, as I believe they not only the interests of the educated Native and European plan whom I have the honour to represent, but also the interests of voiceless millions of native cultivators who are as yet unawar the heavy burden under which they are laid. We agree with Chamber of Commerce "that if India is to be saved from ruin she is to prosper, cheap capital is absolutely necessary to dev her great resources"; but we go further than this, and main that not only cheap capital is necessary, but also a rupee at its nat value in order that the export trade, which is the backbone of prosperity of India, may not be handicapped.

Our two chief industries are the growing of tea and coffee. teas have to compete with Japan and China. Japan has rece adopted a gold currency, but has fixed her exchange (doubt having this and other competition in view) at the present low ruling in silver standard countries, and is for all practical purp one of them. China has a silver standard, and a practical illustra of her favoured competition with India was recently afforded by starting of the Foochoo Tea Improvement Company, which in prospectus lay stress on "the advantage China now has over I and Ceylon in cheap silver, the exchange value of the rupee exc ing that of silver by fully 25 per cent." But taking the pre intrinsic value of the rupee at between 9*d.* and 10*d.*, and exchange value at 1*s.* 4*d.*, the actual advantage in favour of C amounts to 60 per cent.

In like manner our coffees have to compete with those of Br

d Central American States. Brazil has nominally a gold stand-
d, but owing to bad financing, the milreis (its standard coin) has
llen in value during the past ten years from 27*d.* to between 8*d.*
d 9*d.*, so that for all practical purposes Brazil is a country with a
rrency on a level with that of all silver standard countries. Costa
ica and the other coffee-exporting countries of Central America
ave a silver standard, and consequently with Brazil enjoy the same
lvantages in their competition with Indian coffee as China and
apan have in the tea trade.

The Madras Chamber of Commerce admits "that Indian producers
ill be heavily handicapped in competing with silver-using
ountries by a fixed 1*s.* 4*d.* rupee; but to attempt to fix a lower
andard does not seem to be within the limits of practical politics."
is is this prejudication which we would oppose. In our opinion the
ue solution of the present difficulty lies in the re-opening of the
ints. We believe that if this were done a great stimulus would be
iven to the export trade of the country, and capital would be again
tracted. The only obstacle, which unfortunately has been allowed
overshadow the whole question, is the loss that would be entailed
the Government of India by its home charges. This, we believe,
ould be largely compensated by the increased trade and prosperity
f the country, but if fresh taxation became necessary to meet the
equirements of Government, we as producers would prefer to submit
o a small direct export tax on our produce than to have to struggle
gainst the present crushing handicap in favour of produce from
ilver-using countries.

I have the honour to be,

Sir,

Your obedient servant,

(Signed) GEORGE ROMILLY,

Chairman, U. P. A. S. I.

THEORIES BY A NEW HAND.

Planting Extraordinary.

This time I am breaking out in entirely a new place, but
ave borrowed theory from practice, instead of my usual
ice versâ process. The idea is not originally wholly mine.
have chosen my own title, for it *is* planting extraordinary
nd no mistake. It has practically nothing to do with old
nd established estates. I refer wholly to young clearings,
nd how to get the largest possible crops in the quickest
ossible time without forcing or otherwise hurting the
lants in the least.

It seems a puzzle, but I am in earnest, in dead theoretic
nd semi-practical earnest. It can be applied just as well
o coffee as to tea, though I by no means claim perfection
or the system. It has certain obvious faults; whether
hese are counterbalanced or not by its advantages is for
ny readers to judge.

In planting up new estates, whether of coffee or tea, the
tmost efforts are made to get the whole into bearing as
uickly as possible. It generally takes, however, some three
ears or so before the whole estate is planted, usually for
vant of ready money.

I suggest the simple plan, which is originally that of a
vell-known planter, of planting just double the usual num-
er of plants, and letting them bear till they get too
rowded. Then, after cutting them down to the collar, dig
hem up and transplant to the cleared but unplanted por-
ion of the estate.

Before I go any further, and attempt to meet the chorus
f derision, let me touch on the first objection, *i.e.*, the expense of having to pit double the number of holes. As a matter of fact, pits are, to the best of my theoretic belief, not absolutely necessary.

Pits are used to enable the young plant-roots to roam about freely and pick up all the food they can at the start. The larger these pits, *i.e.*, the greater the area of loose soil round the roots, the better the young plants are supposed to come on. Why not have the whole estate one large pit? In other words double dig the whole clearing, as is the practice in isolated cases in Mysore and elsewhere. The cost is not excessive by any means, and in two years the saving in weeding over pitted land will recoup the small excess of outlay. With the closer planting of tea, it is a trifle cheaper than pitting.

Having settled the question of the extra expense of pitting, I shall proceed. In advocating the planting up of double the usual number of plants, it must be remembered that the result will not be that the plants will be twice as close in feet. If the usual distance for coffee be 6×6, double the number of plants per acre will result in the trees being 3×6. With a view to transplanting in a few years' time, the 3×3 plants should be in rows running at right angles to the slope of the ground. This will render digging out the trees a great deal easier.

I have taken it for granted that stumped coffee or tea *can* be transplanted successfully almost at any age, as this is in accordance with facts, I believe.

The advantages of close planting are several. First, that your maiden crop will be about double the usual one; secondly, that for the next two to three years—according to elevation—the same proportionate increase in crop will be obtained; thirdly, you can transplant the now crowded plants straight into your new clearings, stocking them with three or four year old plants instead of the usual nine sets twelve months' seedlings. The first year after transplanting will of course bring in no crop to speak of, as the stumps will be fully occupied with getting a strong foothold in their new home. The year following should, on the contrary, see your now two-year cleared land bringing in full crops.

The only point to consider now is whether the after career of these stumps will be as good as their younger rivals. Here a deal of practical experience records, with regard to coffee, a decided "No." My reply is, I admit, a weak-sounding one, but I believe the method of transplanting adopted in such cases was utterly wrong. A disquisition on this point would run this paper to inordinate length, so I must merely beg the question. With tea, I doubt if it has even been tried largely. A concluding objection lies in the ill-effects induced by over-close planting in the original cleaning. Though both the objections above are weighty ones, without doubt, yet the only manner in which to arrive at a true conclusion is to carefully sum the respective advantages and disadvantages, and strike a balance.

FERTILIZATION OF THE COFFEE FLOWER.

III.

CROSSING operations being completed, the next step would be to select a suitable piece of land for the cultivation and trial of seedlings raised from the crossing plot. It is in this final stage of the experiment that the exact result of cross-fertilization would become apparent, and not before. But the operator needs to possess patience, for among 10,000 seedlings cultivated there may not be *one* showing real improvement in every respect. With our limited experience in crossing, it is uncertain what would happen, although there is reason to believe that cross-fertilization would induce beneficial variation in the growth and production of coffee.

The land required for testing seedlings of mixed parentage should be of the best quality, and the cultivation should be on a liberal scale also. Area is a matter for the planter himself to decide, as it depends wholly on the extent of his operations. I do not, however, advocate large areas for mere experimental work. When the seedlings give their maiden crop, it will be seen approximately what merits they possess from a productive point of view. But other merits, which may be roughly termed constitutional, will only become apparent after a lapse of time and under different modes of treatment. I can readily imagine that a judicious selection of the fittest would prove a most difficult task, even to an expert. The operations discussed from the beginning until now, when the second generation has borne its first crop of fruit, covers a period of about six years. This is a long time, and some men would doubtless say "is the trouble worth the candle? Especially as there is nothing to prove that much good would come out of it." In answer to such a remark, I am pretty firmly convinced that good would come out of it and have already planted up a small crossing-plot with the view of raising hybrids. The plot consists of 130 bushes, and includes *C. arabica, C. liberica* and the "variety maragogipe." A few of the bushes are already well advanced in growth, so that the first batch of crossed seedlings may fruit within five years from date. But when matured bushes can be cross-fertilized this season, the results might be known within four years, which is not very long for a young planter to wait.

My object, so far, has been to explain the *modus operandi* of fertilization rather than to discuss side-issues bearing on its application to the genus *Coffeæ*. But now, I may refer briefly to argumentative views on the latter question. As the coffee bush possesses a hermaphrodite flower, it may be held by some that crossing is neither possible nor desirable. But it does not follow that a flower is self-pollinated because it contains both sexes. In numerous hermaphrodite flowers the sexes attain maturity at different periods, and in all such cases self-pollination is effectually prevented. That dichogamy prevails to some extent in the coffee-flower is certain, as I have often observed stigmas in the receptive stage when the anthers had not dehisced. I am unable to say, however, if this is a general condition, or if it only happens in occasional flowers. A flower may thus be structurally hermaphrodite and functionally unise Then, the sweet-scented coffee flower offers great attra to insects, which is a pretty sure sign that the dispers pollen is favoured by Nature. Indeed, the condition pollen is such as would adhere readily to the hairy lin insects. It is not of the fine powdery kind (so-called of flowers) that would be suspended in the air or li carried by the wind.

Considered, therefore, from a morphological standp there is little doubt but the genus *Coffeæ* is subject to fertilization, and that its flowers are entomophilous.

Lastly, I wish to dispel the idea that established can be influenced one way or the other by operatio crossing, the results of which are only discovered in a sequent generation.

But it is highly necessary that the planter should st conserve his testing-ground, and not allow any unk seed to be utilised for estate purposes. The golden r the testing or experimental ground is to destroy all inf forms as quickly as possible.

New strains of seeds reserved for trial could be tr separately until such time as their merits are fully estab ed. This is all I have to say on the fertilization of the flower at present.

J.

LIBERIAN COFFEE IN THE STRAITS.

II.

PLANTING AND SHADING.

THE holes having all been filled with rich top soil are ready for planting and have only to await the next shower of rain. Great difference of opinion exists amo planters whether it is better to plant young plant stumps. Some say that nothing can beat stumps, have the advantage of seeing and examining the root stumps, and they contend that a stump requires less and if once planted out develops much quicker stronger than a young plant. "Stumps" are young c trees about one to two years' old which are taken out o nursery and cut off about four inches above the roots; tap root and other roots are carefully trimmed and the stumps are ready to be planted out.

Another way is to plant young trees. Your seedli about six months' old, are taken, with the surroun earth, out of the nursery and transplanted in the fi There are many ways of doing this, but the best way t it is with a transplanter. The best transplanter so fa vented, and mostly in use, consists of a thin coppe zinc cylinder about 4 in. wide and about 6 in. deep faste to a strong iron frame with wooden handles.

This is pushed into the ground and then twisted lifted with the plant and surrounding earth. To get plant and earth out of the transplanter, you push the la down over a piece of wood that fits into the copper sh and the young plant and earth are thus forced out of transplanter. It is then wrapped up in green leaves tied round with lalang and planted out in this state. lalang string and green leaves will soon rot away in

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

round, and the young plant can develop without its growth aving been interfered with, without any tampering with s roots or removal of its original soil, out of which it has een accustomed to draw its nourishment.

You can practise and experiment yourself which is the ost advantageous method. My experience, after having iven many a most conscientious trial to young trees as ell as to stumps, is to put in nothing but young plants, nd *not stumps*. Of course there may be cases where you ave nothing else but stumps, and may be obliged to plant iem; but in that case you should stump your plants in the ursery about two months before you intend planting them ut and then plant them in the same way as young plants ith the transplanter.

The manner of planting I advocate requires a good deal ore time, attention and care than that of pulling the oung trees out of the nursery, stumping them, trimming ie roots and planting them into the ground, but it will epay you a hundredfold. Never hurry the planting, take our time over it and do it with the utmost care and atten-ion. Some people only plant in the early morning, others gain only in the afternoon, then the young trees get at nce the benefit of the cool night, and before the heat of he sun can do them any harm next day they are already overed and shaded. I plant right through the whole day nd shade the plants early next morning. Once a visitor sked me why I did not plant the trees about two ft. below he surface of the soil? Your branches, he argued, would hen all be just above the ground and not, as now, about wo ft. above. Every planter, of course, will be greatly musedat this; but yet I have seen young planters do it, nd it might therefore be just as well to mention here the easons why they should not do this:—

1. The branches would in that case be just as far from he roots as in the other case, and draw their nourishment rom the roots just the same; the roots, however, which in ie usual way draw their nourishment from the rich top soil, ould in the other case have to feed on the poor soil, hich they find two ft. below—in most cases such poor soil iat it would not grow coffee or anything else.

2. The young tree, being planted in a hole, would be rowned after the first heavy shower of rain.

3. A tobacco plant, if you cover it up, will shoot new ots as far as it is covered up, but a coffee tree consists of em and roots; if you expose the roots the tree will suffer, nd if you cover the stem it will rot and cause the tree to die.

Be careful to remember this, for I have seen many young lanters, to protect the roots and to give strength to the oung tree, as they thought, heap up rubbish and earth nnd the stem of the tree, which is almost as dangerous as lanting below the surface of the soil. Be particulary care-il, therefore, to leave the stem above the ground.

The sticks used for lining are still in the ground, and ery cooly can see that each plant is exactly in line and in s proper place.

Many planters say that stumps can stand the sun much tter than young plants and will live over a long drought here young plants would die; but this is quite wrong; thing will stand exposure to sun, wind and weather better an a young plant, carefully planted out and left as it is in idisturbed enjoyment of its original soil.

But whether stumps or plants, they both equally require shade. You can try it, of course, without shade and some of your plants may live over it; but it is quite certain, beyond any doubt, that shading can never do any harm.

The shading is done in many different ways. One is to plant shade trees and to place the young coffee under the protection of their branches. This enables your coffee to always have the advantage of shade and at the same time to get the benefit of fresh air and be open to your inspection; but it has the drawback that you have to plant the shade trees at least a year before your coffee, and that they may take a lot of nourishment out of the ground, which would otherwise go to the coffee. Others say that Liberian coffee will not bear so well under shade and that much damage is done by branches falling off the shade trees, but this is a matter in which everyone must judge for himself.* The system, so far, adopted in Selangor is to shade the young trees or stumps with branches of bertam palms; three or four of them, each about two ft. long, are put in the ground around and over the young plant, which is thus sufficiently protected against wind and sun, until it has taken root in the ground and is strong enough to support itself.

In planting, like everything else, organise your labour. No. 1 cooly will take the plants out of the nursery; No. 2 will take the plants out of the transplanter and put them on the leaves which are intended for wrapping the plant in; No. 3 will wrap the plants in the leaves and tie them together with a bit of lalang; No. 4 will lift the plants and put them in baskets; No. 5 will carry the baskets to the fields; No. 6 will take the plants out of the baskets and put one near each peg.

You will notice that I have not explained the way how to plant stumps except just to mention them shortly; the reason is that I am strongly against stumps and would consider myself guilty of gross injustice were I to say any more about them than to warn young planters against them. Stumps, if they do come up at all, may ultimately, in the most favourable circumstances perhaps, become equally good trees as young plants, but they will never become better, healthier or stronger trees. Given equal chances, the plant will always beat the stump.

One last word of warning in planting: pay particular care to the tap roots. Should the tap root stick out of the soil of the transplanter, when lifted out of the nursery, cut it off; if you don't, the root will get crooked and twisted and your young plant will never become a strong and healthy tree. Years afterwards, when you have spent time and money on your plantation and paid a lot of care and attention to a sickly-looking tree, you will discover, when you at last pull it out of the ground, that the tap root had got twisted in planting, and all the care and attention paid to this tree, all the energy and money spent on it, to say nothing of your valuable time, have been wasted and thrown away. Therefore be careful in planting; a mistake or carelessness committed in planting will perhaps only show itself two or three years afterwards, when it will be too late for remedy.

(To be continued.)

* I am of opinion that we require shade trees for our coffee in Selangor. It will, no doubt, bear less crop under shade, but the trees will bear a more regular crop and will last much longer. Without shade trees, especially on hilly ground, I am of opinion that coffee planting will in the long run not prove a success in the Malay Peninsula.

DISTRICT ASSOCIATIONS.

WYNAAD.

PROCEEDINGS of a General Meeting held at Meppadi on 2nd February 1898. *Present*:—Messrs. R. K. Walker (*Chairman*), C. E. Abbot, H. Atzenwiler, B. Behr, E. H. F. Day, J. W. Hockin, D. Mackenzie, W. R. M. Mackenzie, B. Malcolm, E. H. Powell, G. Romilly, S. Robinson, M. D. Taylor, H. Waddington, A. West, and E. DeFonblanque (*Honorary Secretary*).

Proceedings of last meeting were taken as read. *Revised Rules.*—The revised rules were laid before the meeting and discussed. Proposed by Mr. W. R. M. Mackenzie, seconded by Mr. H. Atzenwiler, that the revised rules be adopted and printed for circulation among the members of the Association. Carried. *Roads.*—Resolved that the Hon. Secretary be requested to address the President, District Board, Calicut, to point out to him that the Wynaad Planters' Association has, through the United Planters' Association of Southern India, already addressed the Chief Secretary to Government requesting that the Department of Public Works should resume the upkeep of the Calicut-Choladi road; and to request him to assist them in their endeavours. Read letter from the President, District Board, Calicut, stating that the grant towards the upkeep of the Chundale Sultan's Battery road will be reduced. Proposed by Mr. J. W. Hockin, seconded by Mr. H. Atzenwiler, that the Hon. Secretary, in acknowledging the President's letter, be requested to point out that the Sultan's Battery road is already in a very bad condition, that the main traffic of grain for the district is along this road, and that it will become impassable for such traffic during the next monsoon unless extensive repairs are taken in hand at once. Carried.

Pudupadi Hotel.—Read letters from Mr. T. J. Ferguson and C. Shangran. Proposed by Mr. J. W. Hockin, seconded by Mr. W. Mackinlay, that if C. Shangran builds a new stable south of the Government road and re-thatches and repairs the bungalow, all at his own expense and within the space of three months, the Association will pay him a salary of Rs.15 per mensem, after completion of the above work, as long as he conducts his business to the satisfaction of the Committee of the Association. Amendment by Mr. H. Waddington, seconded by Mr. E. H. F. Day, that the matter be left in the hands of the Committee. For Amendment 6. For Resolution 9.

New Members.—The following new members were elected: Dr. Barboza, Mr. D. J. Duncan, Mr. Douglas Jackson, Mr. J. C. MacDonald.

Sultan's Battery Post Office.—Resolved that the Association petition the Postmaster-General to make the Sultan's Battery Post Office a sub—instead of a branch—office.

Money Order.—Mr. Romilly called attention to the fact that the Post Office did not fulfil its obligations in paying Money Orders promptly, and cited as an instance that money sent from Calicut on 25th January was only paid by the Meppadi Post Office on 31st January. Members are therefore requested to give notice in writing of all similar cases to the Hon. Secretary, so that the Association can approach Government on the subject, as the Planting Member of Council refuses to interpolate Government on one isolated case. A vote of thanks to the Chair closed the proceedings.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (February 4, 1898) says:—The supplies brought forward in Auction this week have been on a moderate scale and valves in most cases ruled unchanged to rather easier.

No East India was offered.

Central American kinds consisting chiefly of Columbian met a fair demand at barely previous rates, but five colory Costa Rica attracted keen competition and realised extreme prices.

The Terme market has continued quiet during the week, and quotations at the close show little change since our last, an estimate of 4¼ Millions for the new Santos crop having very little effect, as it was considered far too small to be at all probable.

Messrs. Wm. Jas and Hy. Thompson's Report of the Colonial Marke
the Week ending February 2nd, 1898, says:—Bank rate 3°/₀. Bo
Exchange closes at 1s. 3 1/16d. Brazil Exchange 6 7/32d. Rupee
3½ °/₀ 63⅜. Silver 26 1/16d. per oz.

Very full prices continued to be paid for fine colory kinds whic
again dearer; other qualities, however, are slow of sale and some
lower at the close. Fine new crop Costa Rica met with keen compet
Brazil markets are steady at the decline. Daily receipts averaged 1
bags in Rio, and 12,700 bags in Santos.

Futures have been dull throughout the week, but close firmer at a
advance, viz.:—Good average Santos in Havre, March delivery, fcs.
in Hamburg pf. 30¼, and No. 7 low ordinary Rio in New York $5.65.

To-day's London official quotations are:—

	Jan.	March	May	July	Sept.	Dec.,
SANTOS ...	30/-	30/3	30/9	31/-	31/3	31/6

Ceylon. The week's auction was heavy, comprising 33,095 packages, and although meeting with good attention from buyers, some slight reduction was noticeable in values, especially in medium Teas, which were distinctly weaker. The Official Wire from Ceylon gives exports to U. K. for January as 8,000,000 lbs., against 7,250,000 last year, and estimates the quantity for February as 6½ to 7 million lbs. Average for week 7·72d., against 8d. same period last year.

Ceylon Tea sold on Garden Account 1st January to date 1898, 1,417 14pkgs., av. 8·12d. 1897, 112,786 pkgs., av. 8d.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 11th March, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Coorg.

POLLI BETTA, 28*th February.*—*Weather.*—Fine with east wind at times. Clouds put in an appearance again to-day. Good rain at any time inside the 15th proximo would ensure good crops. *Crops.*—Last crop all over. Pruning nearing completion. Manuring in hand. *Labour.*—A commencement in paying off labour will probably be made by the 12th proximo. *General Health.*—Some improvement in general health.

Nilgiris.

COONOOR, 24*th February.*—*Weather.*—Fine again now with the high winds we usually associate with March. *Crops.*—Good blossom out in one or two estates. Tea coming on rapidly after pruning unpruned fields flushing heavily. Grain rates still high. *Plant-diseases.*—Generally conspicuous by their absence. *General Health.*—Fairish. *Interesting Items.*—Coast prices for coffee are Rs.9-8 to Rs.9-12 parchment, and no keenness to buy even at these rates. Three to four years ago prices were as high as Rs.15 to Rs.17.

NELLAKOTTA.—2*nd March.*—*Weather.*—The rain of 15th ult. was very partial, varying from nearly an inch in the east of the district to 4 cents in the extreme west. Large blossom out in a few instances, but only a sprinkling on the majority of estates. A good downpour in a week or ten days would be just opportune. *Crops.*—Coffee crop over, probably the worst on record. The coming crop promises to be a very fine one. Trees in excellent heart, and a mass of healthy spike. All depends on timely rain. *Plant-diseases.*—Coffee has been singularly free from leaf disease all through the season. *General Health.*—Fair. Colds prevalent. *Labour.*—Most estates have paid off, pruning in some cases having been deferred. *Interesting Items.*—Difficult to find in this "land where all things always seem the same"—

except coffee! One estate is opening largely in tea this year Fifty acres were opened last season, and this is looking magnifi cent.

PRODUCERS Versus TRADERS.

The Exchange Question.

The movement that the U. P. A. S. I. has set on foot to effect a reversal, if possible, of the present disastrous currency policy, has met with singularly ill-informed criticism from the press of South India. That this was inevitable we can easily understand from the fact of the Presidency papers being almost completely out of touch with needs of the producing classes. The fault, if it is fair to call it a fault, is natural enough. Newspapers are business undertakings, and have to cater for the wants of their subscribers, adopting the principle of serving the interests of the greatest number. Outside the ranks of planters, we venture to affirm that subscribers to the daily papers are rarely found among the agricultural classes. It is the educated and professional classes, business men, lawyers, Government servants and others, who form the great bulk of subscribers. Under these circumstances, it is not wonderful that when the most educated section of agriculturists, the European planters, attempt to speak out for the producing classes of the country, they are woefully misunderstood. They are accused of seeking their own profit in the general ruin of the country, of incapacity to understand the requirements of their own trade, and a lot of other absurdities of the same nature.

And why should such bad faith be imputed to them? Simply because they, in common with all Indian producers, want a cheap silver currency instead of the artificial rupee so desired of export merchants and Government. The public cannot grasp the fact that the interests of planters are identical with those of the rest of the agricultural classes. We are more charitable than our critics, and attribute such lack of understanding to ignorance rather than malice.

The *Madras Times* doubtless voices the opinions of its particular public when it attempts to separate the interests of agricultural labourers from those of their employers. Our contemporary boldly affirms that a high exchange must necessarily result in the higher purchasing power of the rupee in India. With regard to the labouring classes, the higher purchasing power is almost nil, for what do they consume of Europe goods? Indirectly food grains may be cheaper, by the stifling of exports and consequent temporary surplus. But this would be soon corrected by the necessary shrinking in cultivation due to lesser profits.

The *Madras Mail,* which has always shown itself a staunch supporter of planting interests, does not express an opinion on the matter directly. It allows instead "an acknowledged authority on Indian finance" to deliver himself of as acrid and misinformed criticism as it has been our fortune to read.

The arguments employed in the first half of the article are disingenuous to a degree. The great contention of Indian producers is that the present artificial state of the rupee acts as a crushing indirect tax on exporters. With a low "natural rupee," exporters could well afford to have a small direct tax imposed to recoup Government its loss on exchange, as the increase in rupee profits would be comparatively enormous. It is puerile, therefore, to assert that planters propose encouraging and discouraging expor in the same breath. Every agricultural industry in t country would be in the same boat. The sugar produce of Madras and the North-West, to whom the *Mai* "financial authority" appeals, would benefit just as mu as coffee or tea or wheat producers, though in a differe way. A low exchange would act as a very effectu duty on imports of foreign sugars, while at present exact the reverse is the case. The same writer then touches tea, and asks planters if they wish to send tea to Englan Their answer would be a little different to what he expec For England is overstocked as it is. The English mark is no longer big enough, and the chief endeavour now is conquer new markets in America, Russia and on the Co tinent generally. China has been practically ousted fro England, but her total tea exports are none the less ju as big as ever they were. Likin, export duties and wh not—the knowledge of which as they affect the China t trade is not confined to "financial authorities"—China still in almost full possession of the world's markets ou side of England, and the higher exchange goes, the le able will Indian planters be able to oust her. Briti energy combined with "perfect freedom" of trade c accomplish anything. But where is this "perfect freedom in a land where an inflated rupee acts as an almo overwhelmingly huge export tax?

Much has been said on the currency of competi countries, and the arguments used are of undoubted weig Yet whatever their currency, it would not alter the fa that in Indian agriculture the purchase value of the silv rupee remains practically undisturbed by the fluctuatio of exchange.

The *Mail's* financial authority then touches on the effe of exchange on the sterling price of produce. It is a ca of *post hoc propter hoc* argument with him. Because pric for tea fall currently with the fall in exchange, *therefore* t two are indissolubly connected. Delightful logic! L him turn to coffee, and see how his theory will help hi Again, if low prices are paid in years of low exchange, w do not they rise when the exchange is high? Truly gre is this authority on Indian finance.

NOTES.

Mati tea. From a recent case in the Lond Law Courts, we learn that an attem has been made to develop the sale of Mati or Paraguay t in England. So far the success has been inappreciable.

Light railways in Ceylon. In the railway extension p gramme of Ceylon, which is expect to be taken in hand in the n future, we note that out of the four new lines three are the light 2 ft. 6 inch gauge. Their cost varies fr Rs.30,000 odd per mile to Rs.57,000, according to t difficulties of the route.

New Caledonia. The French are doing their b to encourage tea-growing in N Caledonia, the climate and soil of which is said to admirably adapted to the product. That may well be, b tea, more than any other tropical culture, needs che

labour. We have no fears that the French Colony will ever prove a serious rival to British-grown teas.

Tea prices and exchange. In the Ceylon Planters' Association Annual Report for 1897, we notice that the Colombo average price fell to 34⅛ cents as against 41½ cents in 1896, while the London market fell to 7¾*d.* against 8*d.* in 1896. The average exchange in 1897 was 1/3 21/32*d.* against 1/2 10/32 in 1896. The latter exchange at the 8*d.* average would equal 55·888 cents gross value, against 49·499 cents at 7¾*d.* at the higher exchange. Similarly Colombo tea in 1897 at 34·12 cents would have equalled 5·34*d.* against 41½ cents or 5·94*d.* in 1896.

Rubber. Rubber still remains king, says the *Produce World*. At the last sales there was only a moderate supply on hand, while there were numerous inquiries, consequently prices all round advanced 1*d.* to 2*d.* per pound. There are also indications of still further improvement, as fears are expressed that future supplies will not increase in ratio with the demand, owing to growers commencing to bleed their rubber trees too early in their anxiety to share in the good prices now being obtained. Growers will do well to remember that it is fatal to bleed trees too early, and that with a little more maturity rubber plants give much better results.

Various products. From a home exchange we learn that at the last sale of *cardamoms* on the 20th January, it was thought prices would show a slight fall, but after the first few lots a brisk competition set in, and not only were late prices fully maintained, but in many cases an advance of 2*d.* was obtained. Mysore realised as much as 4*s.* per lb., Malabar 3*s.* 9*d.*, and Long Native 3*s.* 7*d.* The *Cocoa* market, just now, is very favourable to shippers, as, though large supplies were to hand at last sales, especially of Dominica, all kinds were dearer than at the previous auction. *Gums* of various kinds, just now, are too plentiful to command good prices, there being nearly 6,000 more packages in stock than at this time last year and very little demand. Ghatti is particularly plentiful.

The Indian tea crop. The original official estimate by the Indian Tea Association of last year's crop was 156½ million lbs. odd, this was revised to 148 M., while the actual outturn was 148¼ M. Of this amount Assam contributed 58 M., Cachar 20¾ M., Sylhet 25½ M., the Dooars almost 24 M., Darjeeling 7¾ M., and the Terai 3¾ M. The remainder was made up from Kangra, Dehra Dun and other districts.

The total sailings from the 1st April 1897 to the end of January were a little over 141½ M. against 138 M. and 128⅓ for the two previous years. Shipments to Great Britain are almost 129 M. against almost 125 M. last year. Australia still shows a slight falling off, as also does America, compared with last year.

Coffee and cardamom husks. Not long ago, states an exchange, there was a good business done between Colombo and the Persian Gulf ports in coffee husk, which was practically refuse thrown away by planters after pulping and cleaning the coffee berries. The Arabs, especially, make use of the husk in place of the civilised preparation of café noir. We now hear that, besides coffee husks, dried cardamom husks have a marketable value, and that shipments of these are being made to some Continental ports. In grading the cardamoms, the "splits" are utilised for this purpose after "seeding" them, and the husks can be placed on the market without being thrown away as refuse. Planters would do well to note this fact, and, in sending the different grades, to add "husks" to the existing classification.

Scientific planting. In another column will be found a vivacious criticism by "Errin Gobra" on a recent editorial on the manuring of estates. We quite agree with our correspondent that scientific assistance would be far better than that from a committee of investigation composed of planters. But as it seems that South Indian planters will have none of the former, we suggested the latter plan as a *pis-aller*. It is amusing to note, however, how "Errin Gobra" gives himself away in the latter part of his letter. He begins by implying that every planter knows what manure best suits his estate, and then involves a scientific expert to tell him how to go about it! For all that, logic or no logic, we wish we received more communications on the subject, as betokening an interest in scientific planting that is at present sadly shy of discovering itself.

Coffee in Hawaii. A Ceylon planter brings back an attractive picture of coffee planting in Hawaii, which our readers will remember was the scene of the famous lady-bird experiments. On his way to 'Frisco, a fellow-passenger on the steamer revealed himself to him as Mr. Caine, formerly of Ceylon, and told him how well he was doing as a coffee-planter in Hawaii. Mr. Hawke was so interested that when he reached 'Frisco he went back to Hawaii, and he now returns from there perfectly enamoured of the place. He says the island is most suitable for coffee planting, and a good acreage is already under cultivation, growing in rich volcanic soil—a soil that could not be found in Ceylon anywhere. Labour was plentiful, shipping facilities excellent, and Hawaiian coffee was fetching 80*s.* a cwt. He secured 400 acres of land at an elevation of 2,000 ft. from the Provisional Government, and he returned at once to Ceylon to make arrangements to sell Orien estate and settle down in the Sandwich Isles to plant up his new property. Almost all the coffee there is Arabian.

Coffee and tea in America. The figures showing the consumption of coffee and tea per head in the United States for the last 26 years are interesting reading. In 1890 only 1·10 lb. of tea was used per head, while coffee was fully 6 lbs. In 1875 tea increased to 1·44 lb. and coffee to 7·08. In 1880 tea was a fraction down, *i.e.*, 1·39, coffee was 8·78. In 1885 tea sunk to 1·18 lb., while coffee rose to 9·60 lbs. In 1890 tea rose to 1·37 lb., while coffee sank to 7·83 lbs. In 1896 tea was down again to 1·31, coffee rising to 8·04. The highest *per capita* consumption of tea was 1·54 lb. in 1881, while coffee was highest in 1892, being 9·61 lbs. of wines, distilled spirits and malt liquors, the respective consumption in 1870 was ·32, 2·07 and 5·31 gallons per head; in 1880: ·56, 1·27 and 8·26 gallons; in 1890: ·46,

1·40 and 13·67 gallons; while in 1896 wines fell to ·26 gallon, spirits to 1 gallon, and malt liquor rose to 15·16 gallons. Thus it will be seen that the consumption of coffee is steadily increasing, while that of tea is stationary. Wines and spirits are falling in favour, but the consumption of malt liquors is increasing greatly.

Carpentry "Kanaks." The following details may be of interest to our readers. They were given us by a reliable Nilgiri planter; the rates are Coonoor ones.

Some Kanaks.—Cost of withering racks. A rack 45 × 4 = 180 sq. feet per shelf will cost as follows for each shelf put in :—

	Rs.	A.	P.
Carpentering @ 9p. per foot	8	7	0
Ten scantlings each 12 feet long	2	0	0
Nine feet of uprights of Bluegum	0	12	0
Eighty bamboo-reepers @ 5	4	0	0
Total Rs. ...	15	3	0

say 16 pies per sq. foot. This includes cost of pulleys and boats to draw sheets on and off the shelves.

Jute hessian costs Rs.16 per 100 yards (45 inches wide), or about 2½ pies per s. ft. of rack to cover (*i.e.*) 1 yard costing As.2-8 covers 3 × 4 or 12 sq. feet.

Buildings.—The following should be noticed. A contractor charging Rs.20 per 100 c.ft. of brickwork and putting in a factory door 6′ × 3′ expects to be paid for the brickwork; the door space occupies (*i.e.*) say 6 × 8 × 1½ = 72 c. ft., besides charging his victim Re.1-4 per sq. ft. for the frame and shutter. This is another one of the iniquitous Nilgiri customs that should be broken through. It is not allowed by the P. W. D.

Writing to the *Planter*, its Coorg correspondent remarks :—

Storage of coffee seed. "I see storing tea seed talked of. How long does tea seed keep? I am prompted to make the enquiry because coffee seed does not appear to retain its vitality long, not even a twelvemonth apparently. This has been discovered after repeated trials. Old planters have not been sure about the matter, and after years have subjected seed to further tests as if deeming previous trials inconclusive, but invariably with the same result, so far as I am aware. It would be interesting to know if others' experience differs from this. It was supposed that seed dried in cherry would retain its vitality longer than in the parchment; perhaps it does, but still in the result it has not been much more satisfactory. I know of seed dried in cherry in December of one year which has refused to germinate in September-October of the following year. Sown in the nursery it all rotted away! and seed got in cherry from Santos went the same way. But seed buried some depth in the ground, even in the parchment, seems to retain its vitality more satisfactorily. At least I know of one case where the seed gathered in December of one year and treated in this way came up with but few exceptions when sown the following September. Contact with earth would appear to be what is wanted to preserve the vitality of the seed, for see how the seed dropped from the trees come up with the setting in of the rains. Some seed, of course, would appear to retain their vitality longer than others, or how else could we account for the successful introduction of other species of coffee into countries separated by great distances from their native habitats? Think of the long journeys that had to be accomplished in the days of sailing vessels."

Salt and leaves. "Plants growing near the sea have thicker leaves than those growing inland. Apparently the sea-salt is the cause of this phenomenon, as plants cultivated in artificially-salted soil produce thicker leaves." Thus writes an exchange. If true, the fact may have an important bearing on the question of rendering coffee immune to leaf disease.

A Mosquito cocoanut plantation. Mr. Rowland W. Cater gives fascinating description of cocoan planting on the Mosquito Coa Our necessarily brief abstract is bereft of much of the cha that invests the original article, but solid facts are wh we want to give our readers. To begin with, sea air, a better still, sea-spray are essential for the well-being the tree. The most suitable soil is coral sand intermix with earth. Nurseries are formed in the usual manner placing sound nuts, in their husk, upright close together rows under a pandal. The clearing and burning of jung is necessary as in all plantations. Bury the sprouted n in pits till two-thirds deep only at a distance of 30 feet ea way. The young plants should have the ground for ten f round kept perfectly clean and well-stirred. Attention this early stage makes the trees bear twice or three tin as early as they otherwise would, some blossoming as ea as the third year. There is no picking of crop; the n fall down of themselves when ripe; the coir of course i valuable bye-product. A minimum crop of 100 nuts p tree may be expected, which is given regularly the wh year round.

Good land on the Mosquito Coast is sold at 5*s.* per ac or leased at three farthings per acre upwards. The c per tree up to the fifth year will be 5*s.* The capi required to produce one thousand nuts will thus be £2-1 Harvesting costs 2*s.* 6*d.*; freight to London £2, whi deducted from the London price of £4 per thousa leaves a profit of £1-17-6*d.*, close on a hundred per ce annual profit. There are other ways of selling the crop, i by expressing the oil, for a gallon of which it takes nuts, and exporting both oil and oil-cake.

How flowers attract insects. For some time past naturalists ha been exercising themselves over question of what really constitu the attracting element of flowers visited by insects. T result has been that numerous experiments have be performed with the view of settling this point. Profes Plateau, of Belgium, has devoted considerable time a attention to such experiments, and his conclusions distinctly interesting. In the "Bull de l'Aacd. Sciènces de Belgique," he sums up the results of investigation :—

In seeking for pollen or nectar, he says insects are guid only to a subsidiary extent by the sense of sight. Th continue to visit scented flowers after the coloured pa have been almost entirely removed. When flowers of same species vary in colour, they exhibit neither prefere ces nor antipathy for one colour over another. Inconspi ous flowers, hidden among foliage, attract large numb of insects. Artificial flowers made of paper or calico, ev when brightly coloured and closely resembling real flowe are not visited by insects; but they are when made green leaves which have a vegetable scent.

If flowers which have little or no nectar, and which therefore habitually neglected by insects, are smeared w honey, insects are attracted in large numbers. On the ot hand, if the nectar is removed from flowers habitua visited, their visits cease at once. The author has p especial attention to entomophilus flowers, and finds t their exemptions from the visits of insects is due mainly their not providing them with honey. From all these fa

Plateau draws the conclusion that the guiding sense to ects in visiting flowers must be chiefly the sense of smell.

London "Times" n exchange.

In discussing the question of "A Gold Standard for India," the writer of the *Times* article on Indian affairs 's: "The truth is that there are three parties to the ques- n, each of which has its own interests to consider. The st, and the most powerful in this country, is the British nufacturer and the Indian merchant in British goods, o naturally desire to sell to India as much as they can, d who wish to keep up or to raise the sterling equivalent the rupee. The second is the Indian producer, who has compete with rival producers in the silver-using countries the tropics, and who finds himself placed at a disadvan- ge if the rupee is artificially raised in India. So keenly is is felt that, in the great British Indian industry of tea- nting, companies will sell in the London market, while lowing so much more profit in their yearly forecast for ch farthing or rise in prices, also estimate so much less of ofit for every thirty-second of a penny in the rise of the pee. These two interests, namely, those who produce in gland and wish to sell in India, and those who produce India and have to sell in competition with the silver-using untries of the world, naturally take an opposite view of easures intended to bear up the exchange value of the pee. The third party is the Indian Government, which s to discharge large gold obligations to England for loans d other payments, and which desire to do so with as small number of rupees as possible. Whatever may be the tails of the scheme now under the consideration of the overnment, this conflict of interests should never be lost ght of. In any practical measure it will certainly have to reckoned with. The problem is not only complex in itself, t it involves consequences of the most serious import to nglish manufacturers on the one hand and to Indian oducers on the other. Meanwhile the railway towards londike, and the 74¼lb. mass of gold reported from beria, open up possibilities of change in the market ratio the metals which, though not likely to produce any mediate tangible effect, cannot be entirely overlooked."

ne and low grades of coffee.

In an article dealing on the difficulties of grocers in purchasing suitable grades for their customers, e *Grocer* writes in its issue of 5th February :—"For several onths past, and particularly within the last few weeks, ices of coffee have diverged more widely apart than ever, ose for the finer qualities advancing still higher, while e current rates for inferior and desirable sorts have escended to a lower point than in 1897 * * * * From the ost trustworthy statistics prepared, it appears that it is ite certain that there is a great and increasing scarcity fine coloury descriptions suitable for consumption in is country; and it is said that the production of coffee tside Rio and Santos, which happens to be the very sort e want most, does not augment as it should, notwithstand- g the exceedingly high rates it commands." * * * * ur contemporary suggests blends of good Santos and rime Costa Rica or Guatemala, which would give a rich ick liquor with plenty of aroma, such as would please e palates and suit the pockets of the majority of con- mers. A preparation of the kind thus described could be retailed at 1*s.* per lb., and at the same time yield a profit of 25 per cent. on the original cost.

"It is almost useless to expect a glut in the supply of fancy coffees simply because there is a superabundance of the common grades, as the conditions of soil, climate, and cultivation in one quarter of the globe differ vastly from those in another, and it is precisely in those countries where the crops are spoken of as being the lightest that the quality and outturn are reputed to be the finest, and *vice versâ*. Under these circumstances the trade will do well to secure all likely parcels of clean coffee on as reasonable terms as they can, for, according to present appearances, nothing is to be gained by waiting for freer arrivals of the new crops from the East Indies and central America; and, if accounts are true, consignments this season will probably fall off sooner than they did in 1897. * * * Although there has been a great deal of talk about the severe reduction in prices of ordinary qualities precipitating a material depreciation in the value of superior coffee, the likelihood of such an event is rather remote."

Cultivation of vanilla.

In his report to Mr. Chamberlain on Seychelles, Administrator Stewart says: "The vanilla crop of last year is the largest that has ever been grown in Seychelles—63,000 lbs. The prices ruling during the year on the London and Paris markets have also been most favourable, and the value of the crop has been declared at Rs.9,36,000. The large output of vanilla has given a fresh impetus to its cultivation, and a very large quantity has been planted during the past year. When the country is opened up by means of roads, as will shortly be the case, many acres of vanilla land will no doubt be taken up which at present are uncultivated, owing to the difficulty of transport. In one district alone, the Mare aux Cochons, to which a new road will be opened, there are about 5,000 acres of virgin soil well suited to vanilla. The cultivation of vanilla only dates back to about twenty years ago, and is only now beginning to be thoroughly understood. The Mexican system of allowing the vines to grow under trees nearly wild is almost universally adopted at present, and is a decided improvement on the old system of training the vines on artificial supports. I trust that the new mode of cultivating it will go far to ensure regular crops. Nothing pays better than vanilla. Its production costs the planter Rs.3 per pound, and as prices vary from Rs.8 to Rs.16 the pound, a net profit of from Rs.5 to Rs.13 is the result. This year the average price was Rs.15 the pound. The yield may be taken to be 200 lbs. an acre. Taking, therefore, an average of Rs.10, an acre of vanilla should produce Rs.2,000. Most of the land in Seychelles is in the hands of private owners, and it is difficult to estimate its cost, but it may be taken that land can be bought at from Rs.100 to Rs.200 the acre. It has been stated that landowners are reluctant to part with their land, but I do not apprehend much difficulty on this score, provided that purchasers are prepared to pay ready money. There is some land belonging to the Government well adapted for vanilla cultivation which can be leased for periods varying from nine to twenty-one years. Seychelles is unfortunately almost a *terra incognita*, for I cannot help thinking that if the scores of young Englishmen who leave the mother country year after year for other lands knew of it, they would give the preference to an

English colony which offers advantages not to be met with elsewhere for the investment of small capital, say £1,000. In 1882 the yield of vanilla was 2,400 lbs., whereas last year, as stated above, it was 63,000 lbs."

To make a plantation pay.

A Jamaican planter, undismayed by the critical position of the sugar industry of the Island, gives some sensible and encouraging advice in a letter to the *Produce World*. It is briefly to let all land that does not bear a paying crop go out of cultivation. An estate may be of great extent, reckoning in all land under crop—good, bad and indifferent. It may have large total crops, perhaps twice as large as some of its smaller neighbours. Yet for all that it may suffer a direct loss each year. If it costs, say, £7 to grow a ton of sugar, it is as plain as a pikestaff that it is the height of folly to cultivate land that will not produce over the ton. What is it then that induces planters to actually throw away their money on such land? If they devoted all their attention only to such land as yielded a crop large enough to pay all expenses, and yet give a surplus, their present losses would be turned into profits. Did this question only concern sugar-planters, we should not have troubled to discuss it, but it affects coffee and tea planters just as much. What is the cause, we again ask, of such blindness to the first principles of business? It is a very simple one. Planters have got into a stereotyped way of regarding their plantations as a whole, and not taking the trouble to ascertain exactly what each field is yielding. There are always "bad bits" in every estate, an eyesore to the owner and manager and a scoff to visitors. There are also many indifferent fields that also do not pay their expenses. Yet until the manager keeps a separate record of those particular fields, he only has a vague idea that they might as well be abandoned. "Might as well"! Fancy having to remain in doubt on such a point. A few years' records of expenditure and income on those fields would very clearly settle his mind one way or another. It may be urged that an abandoned field in the middle of a plantation would be a breeding-ground for pests and plant-diseases of all sorts. So it might if it were left to grow at its own sweet will. The obvious thing to do is to clear and burn it, planting it up with quick-growing timber trees to act as a shelter belt. If trees of economical value, as regards their crops, could be chosen, so much the better. Camphor, mahogany, nutmegs and a host of other valuable trees might be planted on such land. On a tea-garden, fuel-trees would probably be the first consideration.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton:—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

To be a successful planter nowadays needs other th than sufficed in the old days. Estate accounts, in the ma in which they are usually kept, are woefully inadequat their purpose. Complicated systems are not advoc but there is a very real danger of confounding simp with vacuity.

LETTERS TO THE EDITOR.

YOUNG PLANTS DYING: AN INTERESTING QUERY.

Sir,—It not unfrequently occurs that young plants w have successfully stood their own throughout the hot we die off after the first spring showers.

Is this the result of a sudden expansion or contraction o soil round the rootlets of the plants which tears them— what cause do your most experienced friends attribute result?

Plant

A REMINISCENCE.

Sir,—The 11th February 1889 found me sitting ov "kill." The veriest tyro will readily comprehend wh mean. I was perched upon a hastily contrived "mac raised about 12 feet from the ground. Sitting back to against me was my trusty shikar "Bally Kristna." Cir stances necessitated my allowing B. K. to assume this r familiar position. In front, below, to right and to left, stret a wild expanse of Indian jungle, awful in its primitive gran sublime in its vast loneliness.

We were waiting—Bally Kristna and myself—for "Stripe make his appearance. For an hour we had already waited scene around us remained unchanged; the silence, nov coming almost unbearable, was absolutely unbroken. "S thing" was about, and in knowledge of the existence of "something" lesser animal life all "lay low." The " not 25 yards away, turned its ghastly side (the other hal been metamorphosed into "tiger") red and torn, stained bleeding up to the heavens, in mute appeal for vengea 5 P.M. passed, 5-30 passed, 5-45 passed, when—"click," a had snapped. SCIENCE FOR PLANTERS.

Sir,—In your editorial *re* "Manuring of Estates" in *Planting Opinion* of the 12th February, and the suggestion a Committee be organised to trot around collecting informa I regret to say I am one of those "rapidly" decreasing that say "with sublime confidence that every man know methods of manuring that best suit his estate."

s you say, "exposure, quality of the soil and subsoil, fall," to say nothing of altitude, temperature and aspect, uld be carefully compared. Now I ask you, how many men ong us are capable of even finding out the percentage of h a simple substance as lime in our soils? Or even to ertain the physical properties of a soil. And after having an analysis are capable of saying, with any degree of cer-ty, that such and such a manure will give such and such a ult. And where are you going to get the "men of known ity and integrity" to bum around for three months from rg to Cape Comorin? And having visited and interviewed me half-a-dozen or dozen representative ones," who will dertake the labour of love involved in tabulating all the rmation gained? And who would follow their recom-ndations?

Of what practical use are the systems of one district to those another? Will the system of working and manuring on s in the Nilgiris at 6,500 feet help Wynaad or Tinne-ly at 1,000 feet, or even a man at Gudalur? A system of k and manuring carried on on one face of the Baba Boodem s not pay on another.

And what is the use of collecting the information? Will you a collection of solid petrified facts for a series of years? d if you do get them, will they be of any value unless you o get the rainfall, length of the monsoon—and of the ought—the temperature, and goodness knows how many other ditions that are necessary to make the facts of any value?

How many of us have analyses of our soils, and know their ysical or mechanical condition, and have any but the vaguest a of what they need?

One man swears by cattle-manure, another oil-cake and bone, d a third on nitrates and supers. They all contain more or s what is required for growing coffee and getting paying ps. Nine out of ten don't know what the chemical con-tuents and actual money value of the manures they use are. ey stuff in manure, as it's hopeless trying to do anything thout it, and are governed more by what is most easy to get and t out than anything else.

If you will allow me to make a suggestion, instead of letting a avelling Committee loose among us, I say go down to the bed ck. Let the Associations engage the services of one or more entific practical Agricultural Chemists—ones that can analyse ils and manures and have had practical training and ex-rience in all the most up-to-date systems of scientific agricul-re, and are able to apply their knowledge to the changed condi-ns in which they will be placed. Let them for a small fee (in dition to the stipend paid by the Association) analyse soils d any manures we may have offered us and give us advice as what should be done to the former and paid for the latter, d what should be avoided.

To aid the Chemist, anybody requiring his services must, of cessity, give him all particulars as to climate, altitude, system rried on, manures used and results obtained. Let the Chemist bulate these, adding the recommendations made by him and e results obtained. Here you will get a system, and many en will take the advice of an expert for which they have id, when they won't of a brother planter, however good may be, and results will be recorded and a basis for further vestigation established. And then—why, then, we shall have mething to go on with, and when we have found out every-ing, and are only looking out for the millennium some cuss ll go and invent synthetic coffee and——But we have not got ere yet. What with "Nitrogen noodles," "Tara-rara boomed ade," Any port in a storm "Cocky olli birds" and Leaf-seased qu——acks, "Ye dunno where ye are" in Coffee—t just yet, not by a long way.

"ERRIN GOBRA."

GENERAL ARTICLES.

THE MADRAS AGRI-HORTICULTURAL FLOWER SHOW.

THE annual flower, fruit, and vegetable show was held at the Society's Gardens, at Teynampett, on Saturday, the 26th February 1898. The attendance in the early morning was not so good, neither was the show of vegetables as large as in previous years. The arrangements, however, were, as usual, all that could be desired. H. E. the Governor was not present on the occasion. It will suffice for the purpose of a report if we confine our notice to the prize list enumerated as extras offered by the Society and awarded by the judges, with their remarks thereon.

A gold medal for the best sample, and a silver medal for the second best sample, of tea, so moderately priced as to be suited for general consumption. Gold medal awarded to Glendale Tea Estate. Silver medal not awarded.

For the best collection of Green Forage.—Rs. 10, divided between the Saidapet Farm and the Government House.

For the best collection of Vegetable Oils.—Rs. 10. Two exhibitors, Nos. 7 and 3. The prize is awarded to No. 3, as displaying a larger variety, also showing the sources from which the oils were obtained.

For the best collection of Fibre plants and cleaned Fibres. The fibres must have been recently cleaned. No prize will be awarded for an old collection.—Rs. 15, Moonesawmy Mudally. Two exhibitors, Nos. 4 and 5. No. 4 exhibits about 50 varieties of cleaned fibres, including fibres of Bohemia Nevisa (Rhea) and other interesting fibres, is awarded the prize.

For the best collection of Economic Plants growing in pots, such as young timber and other useful trees.—Rs. 15, Mr. C. J. Hay-Ellis.

For the best collection of Dyes, Tanning Materials and Mordants.—Rs. 10, divided between S. Soobaroyloo and Saidapet Farm. Rs. 6 to the former, and Rs. 4 to the latter.

For the best collection of Food grains other than Paddy.—Two exhibitors. The prize is awarded to No. 2 collection as being the best, and showing a larger variety.

For the best collection of Bazaar Medicines.—Rs. 10. Two exhibits, Nos. 6 and 9; both are large collections and are of equal merit. The judges recommend the prize being divided between the two competitors.

For the best made garden pots, pans, &c., of plain and fancy varieties of local manufacture, Rs. 10. There are four exhibitors. No. 4 is awarded the prize; the articles exhibited being well turned, of good finish, and displaying a large variety of novelties. Among the exhibits is one by Messrs. Henke and Co., of Calicut, who show a very fine collection of artistically finished flower pots and vases, which are displayed only for exhibition.

Messrs. Parry and Co., the Madras Agents for Jadoo, Limited, issued some leaflets about this fibre, from which we gather that this "fibre is recommended as a forcing material for tea, coffee and other nurseries, and as a mulch for protecting the roots of plants in hot, dry weather, and trees in a poor dry soil. In this manner it keeps the roots cool, and increases root growth, which greatly benefits the trees and plants."

SOME "NEW" PLANTATION PRODUCTS.

Cacao. In the annual report, the forty-fourth, of the Planters' Association of Ceylon for 1897, there are some interesting notes on certain products which have, most unwisely, received but scanty attention in the South Indian planting districts. In the report we learn that the 1897 cacao crop of 35,000 cwts. was 1,200 odd larger than any previous year. The market is firm and rising, the consumption being apparently greater than the production. The cacao disease or canker, which is now being investigated, is held to be a fungus attacking the bark of trees, and is observed to be more active after the North-East rains. It is especially fatal to the Ceylon Red Cacao or Criollo, but the Forasteros seem immune so far from its attacks. The statistical position at home is very sound, the deliveries for the past few years having far exceeded the imports, the stocks held in London and Havre now being only 160,000 bags against 271,000 in 1896, 265,000 in 1895 and 210,000 in 1894. Prices for Ceylon, in sympathy with those for all other growths, with the exception of fine grades, are fifty per cent. higher than during the previous year.

Rubber. The lower tea districts in the Island have now a considerable area under rubber, the Kalutara yield from the older trees of 3 to 4 lbs. per annum being highly remunerative considering the small cost of cultivation. It takes, however, eight to ten years before yielding crop.

Cocoanuts. The season has been a particularly favourable one, owing to no long-continued droughts. The crop consequently was larger than 1896, which prices have been well maintained until the close of the year.

Cardamoms. The cultivation of cardamoms during the past three years has received considerable attention in the few districts where this product is found to grow profitably. These are principally within the Kandy radius at elevations from 3,000 to 5,000 feet; Medamahanuwara, Nitre Cave, Matale, and Hewaheta districts showing about the largest acreage. In many districts a good deal of this cultivation has been abandoned, or cleared out for tea and other products during the past ten years, where it was found unsuitable and gave but poor returns. The cultivated acreage last year (not including native gardens) was only some 5,000 acres, and this includes a number of young clearings. Going back to 1880-81, cardamoms were quoted at over 9*s*. per lb. in the London market, but fell in price steadily each year till 1895, when they went down as low as 1*s*. 10*d*. per lb. However, during 1896-97 prices again advanced in favour of growers, and the London market is now quoted at from 3*s*. to 5*s*. per lb. for well-cured cardamoms. As curing is rather difficult on most of the estates owing princip weather, the crops are largely sent to Colombo in a or semi-cured, or dry state, and there finally cure shipped to Europe. There is also a good local dema the Calcutta and Bombay markets. The export fo was 463,233 lbs. and for 1897 551,463 lbs., the va which is considerably over one million rupees. Th year's exports show an increase over any previou from Ceylon, and prices realised have been satisfact growers. It is difficult to arrive at any reliable es of the cardamom crop for 1898, as natives are growi product now to a large extent in their villages, and the local market, but it is doubtful if there will be increase in exports over 1897, as that crop w exceptionally good one. Theft of cardamoms, like is still prevalent, and more so where estates are villages. The thieves do much damage when the knives and cut racemes with fruit in a wholesale ma taking green and ripe fruit alike. The only remed these depredations is to have constant watchers.

Rhea, &c. The Committee of the C. having received an offer fr London Company for the treatment of Rhea Fibre a a ton for the Ribbons, felt bound to state in reply tha price offered was inadequate to pay for its cultivati Ceylon, and that the difference between the price o for the Ribbons and the value of the prepared a appeared to be out of proportion. The following are ex from the Governor's message and address to the C Legislative Council published recently in the Goverr *Gazette*:—"It is intended to organise a syste experimental cultivation of economic, rare or new pla the Royal Botanic Gardens, and the increased provis Rs.3,950 practically represents the additional expen required to carry out proposals made by the Director connection with this scheme, it is proposed to atta Scientific Assistant to the Department, and to secu possible, the services of a young man with a traini the study of fungoid diseases for this post. A su Rs.3,931 is included for the completion by Sir J Hooker of the publication of the 'Handbook to the of Ceylon' which was interrupted by the death of th Dr. Trimen." Again, "the encouragement of new pro is an essential duty of the Governor of this Colony. chief interest this year has centred in the Para rubbe the seed of which there has been a great demand, far

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

an the gardens, which form almost the only existing urce of supply, can possibly meet. About 88,500 seeds ve been supplied to planters this year, and many more uld have been supplied if they had been forthcoming. any planters have trees from five to eight years' old, so at in two or three years Para rubber should begin to gure in the list of Ceylon exports. The Forest Depart-ent has also planted a considerable area, and will plant ore, not as a commercial undertaking, but in order eventu-ly to supply seed to the public, who are now taking up the dustry in earnest; 11,500 seeds have thus been utilized is year by the Forest Department. The important fibre lant rhea has received considerable attention this year. he Director of the Royal Botanic Gardens has planted out considerable area with different varieties in some of his ardens. The plant is reported to grow very well, indeed, n Ceylon, and there is no doubt about the beauty and trength of its fibre, but the difficulty lies in its preparation. When this is overcome, as no doubt it will be overcome, he price of the raw material should rise and a very valuable rticle of export would be widely grown. The rise in the rice of vanilla has again attracted notice to this product, nd Mr. Willis has planted out during the year plots of oca, the Ceylon Bowstring hemp, the important West ndian food-plant 'tous les mois' and others. These plants re intended partly for experiment, partly to enable the Gardens to supply larger quantities of the plants to meet ny sudden demands."

If planters of South India could only be induced to take ufficient interest in the matter of new products, we have ot the slightest doubt that the Madras Government would neet them half way in the matter of extending the xperimental side of the so-called experimental gardens on he Nilgiris and elsewhere, while both the Mysore and Travancore Governments would be equally as willing. But planters must first show clearly that they do really vish for such assistance before there is the slightest chance f their obtaining it.

SORTING TEA.

MACHINERY has done much to spoil the sorting of tea. In all the ther processes machinery has improved tea, but in this, which is erhaps a very important factor to good prices, it has helped the anagers to get the work done quickly and cheaply, but it has done way with the old "niceties" of the work. In the old days, when ur tea was about three times the present price, we used to make Broken Orange Pekoe, two Orange Pekoes, two Pekoes, Broken Pekoes, Pekoe Souchong, Pekoe Fannings, Red Leaf Fannings, Pekoe Dust, and Dust; that is to say, eleven "sorts" of tea. And all hese teas used to get different prices, ranging from ten annas as he lowest to two rupees or so for the highest, thus allowing several nnas between the No. 1 and No. 2 of the Pekoes and Orange Pekoes. Nowadays, when perhaps we have only two annas difference between ur best and our worst tea, it may seem absurd to "sort" carefully, nd arguing on these lines, some managers have come down to three orts—Pekoe, Pekoe Souchong and Broken Tea. Each one has ome to his own conclusions, from experience or expediency, and we ave concluded that careless sorting is nearly as harmful as careless-ess in any of the other processes of tea-making. We argue in this ay: If you take five pounds of Orange Pekoe and throw it into 00 lbs. of Broken Tea, you have lost several annas. Suppose that he Orange Pekoe sells for 12 annas and the Broken Tea sells for ix annas, then you have lost $5 \times 6 = 30$ annas. Then by way of xperiment you throw 8 lbs. of Pekoe into 100 lbs. of Pekoe Souchong, he one being sold for 8 annas and the other for 7 annas, then you ave lost 8 annas. Again, if you go further than this and put 20 lbs. of Orange Pekoe into the Broken Tea you may raise the price of the Broken Tea by two pice (= 50 annas), but you lose $20 \times 6 = 120$ annas. It is impossible to be definite; but the conclusion is that you lose good tea by putting it into lower class tea without raising the price of the lower grade; and by leaving lower grade tea in the grade above it, you reduce the price of the higher grade.

No one makes tea so coarse as to have no Orange Pekoe in it; and, however small a percentage it may be, it would pay to separate it from the coarser teas. It is possible to carry this idea too far; for instance, by repeated cutting and sifting through a No. 14 sieve one can each time get tea of the *size* of Orange Pekoe, but all these mixed together would make a very bad Orange Pekoe: it would cease to be real Orange Pekoe after the first cutting, and after that it would be cut up Pekoe and cut up Pekoe Souchong, and these would also be very grey and unsightly. The perfection of sorting is as follows: The whole tea is put over a No. 14 sieve either untouched or gently disintegrated by hand; it must be a hand sieve made of cane and shaken until tea ceases to fall through freely; this makes Orange Pekoe No. 1. The tea above the No. 14 is then passed over a No. 12 sieve, and you get Pekoe No. 1. The tea is now cut up by any sort of machine or crushed by hand and again put over No. 14, which yields No. 2 Orange Pekoe; then over a No. 12, which gives No. 2 Pekoe. The residue is then sifted through a No. 10 sieve, and it is cut up time after time till all goes through. This when fanned makes Pekoe Souchong and Broken Tea. Broken Pekoe is got out of the Orange Pekoe by fanning, also out of the tea which drops

GORTON SHIRTING.

FINE Gorton Shirting, F. No. 4, in pieces of about 80 yards, at 4½ annas a yard.

through the sieves when firing, and nowadays a good deal of Orange Pekoe and Broken Pekoe is obtained by sifting the leaf before firing.

The crudest method of sorting is to cut up the tea with the machine breaker, and put it through a cylinder consisting of a No. 12, No. 10 and No. 8, then cut up the residue, or tailings, and send them through the cylinder again. By this means the work is done very speedily, but the result is that each grade consists of a mixture of each sort more or less cut up. This style of machine accounts for the small difference in price to be found in many marks, between the Broken Tea, Pekoe Souchongs, Pekoe and Orange Pekoe. The Orange Pekoe has Broken Tea in it, and the Broken Tea has Orange Pekoe in it, and so on, but (as stated before) this Orange Pekoe does not improve the Broken Tea, and the Broken Tea spoils the Orange Pekoe. Then, is it worth the trouble, or the expense? That *is* the question to be worked out by each Manager. Looking at the matter broadly, there is about 40 per cent. of Pekoe Souchong and Broken Tea. Of 200 million pounds of our British tea this 40 per cent. represents 8 million pounds. Of this 8 million 3 per cent. is good Orange Pekoe = 240,000lbs., and 5 per cent. is good Pekoe = 400,000 lbs., and if this amount of Orange Pekoe and Pekoe could be placed on the market in excess of our present offerings, it would have a marked effect on the reputation of our tea, and this could be done by more careful sorting without lowering the prices of the Pekoe Souchong and Broken Teas.—*Indian Planters' Gazette.*

DISTRICT ASSOCIATIONS.

SHEVAROYS.

PROCEEDINGS of the Monthly Committee Meeting of the Shevaroy Planters' Association held in the Victoria Rooms, Yercaud, on Monday, the 7th February 1898, at 1 P.M. PRESENT:—Rev. M. Anderson, Mrs. S. M. Hight, C. G. Lechler (*Chairman*), C. Rahm, J. C. Large, R. Gompertz (*Honorary Secretary*).

1. Notice calling the meeting was taken as read.
2. *Read* again Mr. Large's letter of 24th November 1897 *re* small change; read also Honorary Secretary's letter to Collector of 13th January, and Collector's reply of 21st idem, stating that there had been a dearth of small change lately, owing to the large demand for it caused by the famine. *Resolved* that as the pressure seems to have been purely temporary, the matter may be shelved for the present.
3. *Read* and *recorded* letter, dated 22nd January 1898, from Hony. Secretary, Nilgiri Association, in reply to our letter of the 14th idem, stating that the engagement of an Agricultural Chemist would be undertaken by private individuals in the Nilgiri District.
4. *Read* and *recorded* circular from Secretary, U.P.A.S.I., dated 13th July 1897, regarding the re-appointment of the Hon'ble H.P. Hodgson as Planting Member of the Legislative Council.
5. *Read* letter from Mr. Leeming resigning his appointment on the Planters' Committee, as well as his seat on the District and Taluk Boards, and his position as a Special Magistrate for the Town of Yercaud, as he is about to proceed to England. *Resolved* that the thanks of the Association be conveyed to Mr. Leeming for his services on the District and Taluk Boards for the last 18 months. *Resolved* further that the Honorary Secretary be requested to ask the Collector to nominate the Rev. M. Anderson as the representative of the Shevaroy Planters' Association on both the District and Taluk Boards, and to appoint Mr. C. G. Lechler as Honorary Magistrate in lieu of Mr. Leeming, resigned.

C. G. LECHLER, *Chairman.*
ROBERT GOMPERTZ, *Hony. Secretary.*

THINGS SLOWLY LEARNED.

THERE is a man in Scotland who used to write many readable and instructive things. He signed himself "A Country Parson," and a bright parson he is. One of his essays is entitled "Things Slowly Learned," a good line of thought for anybody.

Well, here is one of the things slowly learned—that disease doesn't jump on a man like a wild cat out of a tree, but develops from seeds and conditions, just as roses and weeds do. We who write and print the essays of which these lines are one have this a hundred times; but all the people don't seem to thoroughly grasped the idea yet.

For if Mr. Theodore Treasure alone had done so, he wouldn't suffered ten years from attacks of rheumatic fever. In Nove 1891, he says he had a fearful time with it. He tells us in a that he had dreadful pains all over his body, and was so so couldn't bear anything to touch him. Even the bedclothes him, like a feather against a sore eye. "I got little or no slee says, "tossing all the night long, and trying to get ease shift of position.

"I had a foul taste in the mouth, and spat up a great quant slimy phlegm. My appetite left me, and the little food I down gave me great pain at the chest and sides. For *five n* I was confined to my room, most of the time unable to lea bed, and what I suffered during that time I have no wor describe."

Any one who has ever been through that sort of thing can believe what Mr. Treasure says; for when every muscle and jo a man's body is throbbing with inflammation, it isn't any co collection of words that can set forth his feelings. It is agon torment in the supreme degree. Yet we ought to know bette to have it. But we don't—not yet.

"I was perfectly helpless," continues our friend, "and scarcely move. In fact, the people had to move me from on of the bed to the other. Month after month I was laid u suffering in this way. I had a doctor attending me, but he able to do much to relieve me.

"Finally, to cut the story short, I came to hear of Mother Se Curative Syrup. I read about it in a book that was left house. The book said this medicine was good for rheumatism so my wife got me a bottle from Mr. Ford, the grocer, at Oa After taking it for a week I felt great relief. Then I kept on t it and not long afterwards I found it had cured me; *it had com ly driven the rheumatism out of my system.* I am willing you s publish these facts, and yon can refer any inquirers to me. (Si Theodore Treasure (Waggon and Horses Inn), Doulting, Sh Mallett, November 3rd, 1893."

Now let's hark back a moment. To the thoughtful r Mr. Treasure's story may look a trifle confused and mixed. is, he describes the symptoms of rheumatism proper in conn with a lot of other symptoms which wouldn't seem at the first to have anything to do with rheumatism. But there's Mr. Treasure is right and the reader wrong. His account that he was a victim of chronic indigestion, dyspepsia, and t liver—and that covers the whole ground. Rheumatism (*and the slowly learned lesson*) is merely a nasty symptom of a dysp condition of the digestive organs. At the outset it means too eating and drinking. This results in the formation of a poiso acid which fills the body and produces the local outbreak rheumatism. Hence we cure it from within not from without. this *true* idea is also a *new* idea—do you see?

Try to get this lesson by heart. You can *prevent* rheumatis Seigel's Syrup; you can *cure* it by Seigel's Syrup. But it is comfortable to prevent it.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (February 11, 1898) rs:—The moderate supplies offered in Public Sale this week met a good mand and in most cases previous values were fully maintained.

Nearly 4,000 bags East India were catalogued and attracted good mpetition, ordinary to medium qualities being disposed of at steady ces whilst fine colory grades realised extreme rates.

The Central American kinds brought forward consisted chiefly of mmon descriptions which sold slowly at slightly under valuations.

The Terme market has had a week tendency during the past few days ing to an estimate of ten million bags for the present Brazil crops; t at the close the market is steady at 6d decline from last week.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for e Week ending February 9th, 1898, says:—Bank rate 3%. Bombay change closes at 1s. $3\frac{7}{8}$d. Brazil Exchange $6\frac{25}{32}$d. Rupee paper %. $63\frac{3}{8}$. Silver $26\frac{1}{16}$d. per oz.

The better qualities of all kinds continue to be well competed for, and se rather dearer, whilst ordinary continues dull, and difficult of sale. he larger supply of East India Coffee sold well at full to dearer prices r good, and extreme rates for fine, the commoner kinds being rather wer. Brazil markets remain dull.

According to Messrs. G. Duuring & Zoon the stocks at the European rts on the 1st inst. shewed an increase of 8,050 tons, and the total sible Supply a decrease of 12,330 tons, being estimated at 178,200 tons d 357,670 tons respectively, against 170,150 tons and 370,000 tons on e 1st January.

Daily receipts averaged 12,400 bags in Rio, and 12,400 bags in Santos.

Futures close 9d to 1s lower, viz.:—Good average Santos in Havre, arch delivery, fcs. 36.25, in Hamburg pf. $29\frac{3}{4}$, and No. 7 low ordinary o in New York $5.75.

To-day's London official quotations are:—

TEA.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, dated February 11th, 1898, says :—

QUANTITY BROUGHT TO AUCTION IN LONDON

FROM 1ST JUNE TO DATE.

	Indian.	Ceylon.	Java.
1897-1898	1,196,348 packages.	836,857 packages.	30,489 packages.
1896-1897	1,226,056 ,,	783,921 ,,	28,682 ,,

34,688 *pkgs.* INDIAN
28,182 ,, CEYLON
1,913 ,, JAVA
} Total 64,783 packages were offered in p auction this week.

The total quantity of British Grown Tea taken by the United S and Canada during each of the last six years is shown below, viz :—

	1897.	1896.	1895.	1894	1893.	18
Lbs.	11,361,840	9,623,283	7,816,467	4,723,370	3,981,837	3,07

The steady annual increase amply justifies the expense incurred b Indian and Ceylon Tea Industries. It is most important that the su afforded this new industry should be continued, especially now that Teas are being heavily advertised in North America.

INDIAN AND CEYLON TEA TAKEN BY NORTH AMERICA DURING EACH OF THE LAST SIX YEARS.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c. Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 18th March, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

S. E. Wynaad.

DEVALA, *9th March.—Weather.*—Since the 24th February it is very hot during the day and cool at nights. Since the 5th inst., strong wind is blowing both by day and night. The sky is very clear and there is no sign of any rain. *Crop.*—Gleaning is finished and pepper is being picked. *Grain.*—Salt 8, rice 8, cholum 18 and ragi 16 seers per rupee. *Health.*—Fair. *Labour.*—Sufficient.

Nellampathy.

9th March.—Weather.—Strong east winds for a week now. The shower I last reported brought out a blossom of about three-fourths everywhere, and rain now would suit every one, but there is no appearance of more at present. *Crops.*—Rice, &c., still very dear. *Plant-diseases.*—A little leaf-disease still to be seen on clearings. *General Health.*—Remarkably good for the time of year. *Labour.*—Everywhere paid off and only hot weather coolies—mostly Mulsers—here now. *Interesting items.*—District getting very empty, as few stay here for the hot weather who can get away elsewhere.

Coorg.

POLLI BETTA, *8th March.—Weather.*—Cloudy a day or two ago. Clear before and since. High east wind yesterday, but little dew. *Crops.*—Spike healthy and plenty of it. Bees still on *Sagade* (Schleichera trijuga) flowers, so perhaps it is well that the rain is delayed; but we would like to see it by the 15th or 20th, or at any rate by the close of the month. *General Health.*—Some improvement; but there seem to be always cases of fever and bowel-complaints. *Interesting items.*—Rifle Meeting brought to successful close on 5th; Colonel Robertson's cup fired for yesterday morning; Inspection of B. and D. Companies, S. Coorg, on 10th instant.

DENITRIFICATION OF MANURE—THE OTHER SIDE.

THE results of the recent German experiments on the denitrification of cattle manure, which we summarised some time ago, have met with considerable criticism in the English Press. The chief arguments advanced against the theories drawn from the German investigations is that the amount of cattle manure used in the experiments were immeasurably greater than that employed in ordinary agriculture. Consequently, it is impossible to reason accurately from results obtained under artificial conditions to those likely to be obtained under natural and widely-different conditions.

In the December number of the *Journal of the Royal Agricultural Society of England*, Professor Warrington has an interesting and very detailed criticism on the remarkable experiments described in the preceding number of the same journal. The German conclusions, it should be remembered, were as follows:—1. The solid excrement of the horse or cow is practically valueless as a manure. 2. When applied in a fresh state to land, it destroys the nitrates present, and even those added to it as nitrate of soda, resulting in a crop smaller than that of unmanured land. 3. It has a like deleterious influence when applied in conjunction with sulphate of ammonia, urine or green manures. 4. Straw is even worse than dung in the above respects. 5. The denitrifying action of both is due to the presence in these substances of a special denitrifying organism. 6. When old and humified, the harmful action of dung is much lessened. Further, that the longer the dung has been applied before the addition of the nitrates, the lesser is its harmful power. 7. When preserved by admixture of superphosphate or kainit, its denitrifying power is little altered by age.

We cannot attempt to follow Professor Warrington in his exhaustive criticism, but shall summarise his arguments as clearly as we can. He begins by reviewing the process of denitrification, which has been carefully investigated during the past thirty years. The reduction in nitrates is of several distinct kinds,—from nitrate to nitrite; from nitrate to nitric oxide gas; to nitrous oxide gas; or finally to nitrogen gas. The first form does not necessarily involve any loss of nitrogen, but all the others do, as the product escapes in the form of gas. The bacteria that cause these different forms of bacteria are of various species. The manner in which they work is by bringing about the combustion of organic matter by the oxygen of the nitrate. Circumstances being favourable, the amount of nitrate reduced is determined by the quantity of combustible organic matter present. This combustion can take place without air in the same manner as gunpowder can burn under water. It must be remembered that nitrate is a compound of which oxygen is an important constituent. If this oxygen is used in combustion, the nitrogen of the nitrate is set free or denitrified. In the presence of air, the oxygen taken from the nitrate in the combustion of the organic matter is replaced by the oxygen of the air, so that either the rate of oxidation is greatly increased, or the reduction of the nitrate is diminished. The denitrifying bacteria are present everywhere, and are not confined to stable dung. Air and consequently soil dust contains them in myriads. All they need to effect their work is a suitable mixture of nitrate organic matter under certain favourable conditions.

The greater denitrifying action of horse dung comp with cattle dung is explained by the greater proportio hay consumed. A given weight of hay presents a far gre air surface than a similar weight of turnips, and consequ ly has present on its surface a far larger number of bact These are not destroyed in the course of digestion, and present in the dung in a larger proportion than ever.

By means of experiments which we shall not fol Professor Warrington states that the conditions w bring about a loss of nitrogen by denitrification ar follows. There are needed: 1. The specific organ 2. The presence of a nitrate and suitable organic ma 3. Such a condition as to aëration that the supply of at pheric oxygen shall not be in excess relatively to the su of organic matter. 4. The usual essential conditio bacterial growth, as plant food, and a suitable tempera Of these conditions, the supply of organic matter is b the most important in determining the extent to w denitrification will take place. Experiments have pr this up to the hilt. German experiments on this prin were entirely overlooked, the investigators taking thought of the amount of organic matter, merely confi themselves to the exact amount of nitrogen supplied. nitrogen given in the above experiments were in the of many different substances, each varying greatly in amount of combined organic matter. Thus the dry we of blood containing 2 grains of nitrogen is only 12 gr while that of farmyard manure varies from 65 to that of horse dung is 103; while rye straw is 409. was found that crops manured with blood recovered a l amount of nitrogen,—fifty per cent., while farmyard na only resulted in a recovery of 6 to 8, and horse dung w

The condition of the organic matter is of great imp ance. It must be *fermentable* organic matter to en denitrification to take place. Black humified dung scarcely any effect on nitrates, while if fermentati lessened by means of superphosphate or kainite, the required for the cessation of fermentation is far prolonged.

The proportions of manure to soil in the German ex ments were far greater than in field practice. Conseque though of undoubted interest, they rather illustrate properties of manure under certain conditions, than farmers to expect like results in the field. "Organic m in the soil acts," says Professor Warrington, "in an inju manner only when it is of such kind and quantity th changes the character of the soil from an oxidising deoxidising medium." The usual practice in farming apply some ten tons of farmyard manure per acre, w will amount to 1 per cent. of the soil which will be m with it in practice. Sometimes 20 tons will be gi but 2 per cent. will very rarely be exceeded. Nov Wagner's experiments, the percentage of dung to soil w representing the enormous quantity of 70 tons per His ordinary dressing of dung was 4 per cent., double highest quantity ever used in farming and four times usual dressing. Maercker even exceeds this, for his portion of dung was 10 per cent., equivalent to 100 per acre, and in some of his experiments he exceeded huge amount by three times the last quantity. In

rther experiments, the quantities used were far smaller d the results greatly better. In fact, in field practice, Maercker admits, the usual recovery of nitrogen from myard manure is 25% against the pitiable 6 to 8% tained in his experiments.

In our next issue we purpose to notice the Rothamsted ults bearing on the question.

NOTES.

w mistletoe grows.

We notice a writer in a tea exchange puzzling himself over the nner in which mistletoe effects a lodging in tea. It is very simple matter. Birds are very fond of the sticky it of the parasite, and after digesting the pulp, pass out e seed, which alights in a favourable or unfavourable posin as it happens. When left on a twig or branch, the ckiness of the seed makes it adhere, until sufficient isture causes it to germinate. The tap root, so to speak, netrates the bark and feeds on the juices of the tree. ence the occurrence of mistletoe on all sorts of trees and all sorts of localities. It is said that the best way to adicate the pest is to *break*, not cut, off the affected anch.

namite in clearing and.

We see it suggested in a contemporary that more extended use of dynamite might be made noways in clearing forest land for plantations. The expense clearing out by coolie labour the enormous stumps that sfigure new clearings is certainly prohibitive, while the vantages of blasting them out with dynamite are not few. is alleged that the regular use of the explosive on a earing would entirely obviate the heavy cost of a deep gging, as the ground is loosened to a considerable depth und the site of each explosion. As augers would do the illing of the requisite holes, or ordinary coolies could be trusted with the initial part of the work, the cost per shot" would probably not exceed six annas on an average, d might conceivably be done for less.

e Nilgiri Agri-Horticultural Society.

The next exhibition of this Society is to be held at Ootacamund on the 23rd April. There are 36 small prizes for flowers, aggregating s.124, while the same amount is also offered for vegetables d fruit. Some Rs.27 are to be awarded for farm and field oduce—a very sensible addition to the programme. If might offer a suggestion, we think that medals might be warded to the exhibitors of the best collection of dairy oduce, of Nilgiri jams, also perhaps for tea and coffee t up in marketable form. In addition to the above, the overnment of Madras has offered prizes of Rs.30, Rs.20 d Rs.15 for the three best samples of barley grown on the lgiris, each exhibit not to be less than a bushel. Should barley have been grown by April, the prize will be ferred to the September show.

e Currency question n Ceylon.

The Ceylon planters are joining heartily in the movement started by the U. P. A. S. I. to induce the dian Government to pause in its ruinous currency policy. overnment has admitted that it would be highly dangerous to fix exchange at a higher rate than 1*s.* 4*d.* per rupee, on account of the great loss to the industrial development of the country. Yet, in a most illogical manner, it refuses to consider the loss accruing from an exchange forced up to the limit it has imposed. In commenting on the position, the *Ceylon Observer* brings to notice that as the Indian and Ceylon tea exports only form one-ninth of the whole export trade, the total losses suffered at present by producers is something enormous. Of the estimated total loss of 18 million sterling in 1897, native producers are thus reckoned to have lost *sixteen million pounds sterling!*

Nilgiri tea.

Mr. Geo. Christison, the well-known Darjeeling planter, whom we unfortunately missed during his short stay in Coonoor, gives his opinion thusly on Nilgiri tea: "I like your district in many ways. Your soil generally is very good, and your tea *looks* healthy and well. Of course without being with you all the year round, I cannot form any very reliable opinion. . . . As you must know, your tea has not been in good favour in the London market. This may, I think, be remedied in some measure." We quite agree with Mr. Christison. The capabilities of the Nilgiris are shown in the success of perhaps only two or three gardens at most. The soil is good, the climate very good, but the jat is—mostly—vile. Until a fuller appreciation is shown of the virtues of a better jat of tea than is now commonly grown on the Nilgiris, and until the present style of three acres and a factory are given up, the prospects of the Blue Mountains, as a modern tea-district, will remain ultramarine.

The Russian market.

In 1896 the consumption of tea in Russia was 92 million pounds, of which 52 millions were leaf teas and 40 million brick or slab tea. The population by the census of January, 1897, was over 126½ millions. About 64 per cent. of the whole is imported by land from China, the remainder coming by sea. The import duties are in favour of the land trade, being only 1*s.* 2*d.* per English pound against 1*s.* 10½*d.* if crossing on the European frontier. This is on leaf teas. Most of the Ceylon and Indian tea enters Russia through the Russo-Prussian frontier. Owing to the Russian system of allowing no tea to be sold in retail except when packed under Government supervision, an import trade in packet teas is impossible. The crushing import tax is of course the great barrier against extended consumption of British grown teas. On an average the duty exceeds 300 per cent., *ad valorem*, much of the Chinese tea being worth under 6*d.* per lb. The trade is generally hostile, but despite its prejudices is forced to use Ceylon tea to give strength and colour to its blends.

Spices.

There is, in many instances, a distinctly firmer tone in this market, and at Wednesday's (9th February) auctions Cochin ginger met with a more active demand, particularly fair washed rough sorts, which sold at about 2*s.* to 3*s.* advance on recent rates, and, with a continued good enquiry, a further advance has since been established. The large stock here of Cochin ginger has, no doubt, for some little time past, tended to depress values on the spot, but now it has become apparent that shippers are not disposed to accept correspondingly low prices for the new crop ginger to arrive, a reaction in

values for landed parcels has quickly set in, resulting in an advance of about 5*s.* from the lowest point. Japan ginger is also about 2*s.* to 3*s.* dearer. Jamaica is nominally unchanged, but prices are steady. The market for white pepper continues firm, and at auction 6¾*d.* per lb. was realised for Penang white, showing a further rise, notwithstanding the heavier arrivals of 273 tons as against 78 tons delivered during the past week. Business in black pepper is less active, but quotations remain fairly steady.

Coffee in America. The deliveries of coffee in the United States in 1897 were 5,408,824 bags against 4,555,130 bags in 1896, an increase of 853,694 bags, or 18·75 per cent. This is a remarkable gain, and must be credited, according to the *Grocer*, to two factors, the most important of which is the low cost of the article, and the next the vigorous war carried on by the great roasting establishment, resulting in a heavy increase in the sale of roasted coffee in packages, and which sells at wholesale to-day at 4¼*d.* and retails at 5*d.* to 6*d.* per pound. In the raw state coffee is selling from 2½*d.* up to 1*s.* 4*d.* per pound. The low price has stimulated the starting of small roasting establishments, and as the blending of coffee is very profitable, dealers are pushing the coffee business as never before. As a rule retailers buy coffee roasted, and grind it as wanted. The identity of the bean is almost lost in roasting, and this, coupled with the wide range in prices and varieties, gives the wholesale dealer a rare opportunity for a profitable trade. At retail the finest Padang Interior roasted coffee retails from 1*s.* 5*d.* up to 1*s.* 6*d.* per pound. A very good coffee is retailed, in the bean, at 4*s.* for four pounds.

Adhatoda vasica. After a considerable amount of investigation, it has been decided that after all the insecticidal powers of this plant are not very great. Experiments, while proving that this plant is distinctly poisonous to certain forms of insect life, yet were not successful enough to justify its extended use on tea-gardens. It may be interesting to note here the different qualities possessed by vegetable and mineral poisons. Infusions of tobacco, though of late generally abandoned by horticulturists, have certain distinct advantages over the use of such mineral poisons as the arsenical compounds known as Paris green and London purple. The latter are poisonous to the very end, as long as they remain in a concentrated form, and, in fact, if left long on a plant may seriously injure it. The compounds of tobacco, however, decompose when exposed to the air, and their poisonous properties pass off after killing off the blight. For tea, it is therefore of the highest importance to only use vegetable preparations in spraying the bushes, unless, indeed, such spraying is effected soon after pruning. *Adhatoda vasica*, being a leguminous plant, contains an abundance of nitrogen and mineral salts, and is highly valued as a manure by native cultivators.

Tea Market. *Indians.*—With a continuance of moderate supplies and a steady demand, (*P.M. Review* of 12th ult.,) prices show no material change. Some of the better class descriptions, especially those with a not too pronounced autumn flavour, have sold at full rates, which are likely to be maintained, as fine teas will probably not be over-plentiful later on. The me Assams and Dooars growths (the latter in several showing improved quality) have also attracted attention have fetched fully late prices, and as the former kinds probably not be in excess of requirements, a firmer ma for them is not unlikely. On the other hand, Sylhets Cachar teas, with few exceptions, are of poor quality, are consequently comparatively neglected, even at moderate prices now ruling. The accumulated stoc doubt, comprises a considerable proportion of these k and the demand is not likely to show any material provement until the supply of the more desirable so reduced. Darjeelings are still deficient in the flavour lo for in this growth, consequently the bidding has been s while Travancores, owing to their better quality, have with a brisker enquiry. Of the 34,540 packages catalo for public sale, 31,230 were sold, the demand moderately active for all good useful descriptions.

Ceylon tea in 1897. Messrs. Wilson, Smithett & C their Ceylon Tea Memoranda 1897, do not strike a very high note. The high excha accompanied by a further decline in price to the exte almost a half-penny per lb., does not indeed allow of gratulation. On the other hand, the statistical pos could not be sounder, for while the increase of imports only two millions, deliveries showed an expansion of s millions. Over-production, therefore, is not yet at The increased deliveries, it must be added, were due very large expansion of re-shipments to the conti from where considerable orders are placed on sam received prior to the public London auctions. It is Russia chiefly that these orders come. Nothing glowing can be said about re-exports to other parts o world, though of course this means that the day of d shipments is waxing apace. The danger of shipping in vessels with strong-smelling cargo, such as eucal oil, were prominently brought forward during the several invoices being seriously affected.

Although as a rule three important grades ma regarded as sufficient, and indeed in the case of shipments should not exceed that number, in orde ensure due consideration from buyers, yet the incre number of large invoices may well be further sub-div and include an Orange Pekoe (Unbroken), so that proportion of Broken Pekoe may be more limited increasing demand from the Continent is confine "whole leaf" teas, and Orange Pekoes—wiry and from dust—are well calculated to supply the want foreign markets.

Coffee. At last there has come a che the continued increase in the s says the *P.M. Review* of 12th ult., and during Jan the world's visible supply decreased some 12,000 tons is partly due to the delay in forwarding caused by floo many of the Central American countries. From Costa the new crop is arriving very slowly, and from the l reports it will probably be the middle of March before large quantity arrives. In the meantime, more atte is able to be paid to East India, of which there has a rather better supply. Prices have been well maintai while few lots of really fine have fetched rates higher

iose that were ruling last year. Further shipments of Mysore iow a very irregular outturn: some estates which usually ind very fine quality prove this year to be very inferior, hile others are quite equal to the average. Of other kinds iere has only been a small supply offered, and prices are nchanged, excepting for Santos, which has sold rather wer. In the terminal market prices gave way in the middle f the week, on an increased estimate of the present crop, ut since then there has been some improvement.

The bulking of tea. We have by no means heard the last of this question, which, partly by he action of Mr. Lipton, has now reached an acute stage. Mr. J. Buckinghlam, C.I.E., Chairman of the Assam Branch f the Indian Tea Association, has recently addressed n important letter to the parent branch. Some years go estate bulking was generally practised and in a very efficient manner, but was stopped owing to brokers and others leclaring that London bulking was essential in any case. t is doubtful whether 5 per cent. of Assam gardens now do state bulking, for the advantages and disadvantages eem fairly evenly balanced. In bulking on the estate, one aves time in London in bringing tea to market; on the ther hand a slight loss of time is experienced on the estate. A saving of warehouse charges is effected to the extent of bout 1*s.* per chest, or £73,000 per annum; against this nust be placed the expense of making air-tight bins and he longer fire-risk through storage on the estate. Again he practice effects a prevention of risk of mechanical damage o tea through bulking in England; but *per contra* it ntails a risk of tea deteriorating in bulk even if in so-called ir-tight bins. A further advantage claimed for estate bulking is the lessened liability to loss in weight, test packages nly being weighed; there is no counterbalancing disdvantage on this score. Yet another *pro* is the superior ondition in which the packages reach the buyer; estimating at a farthing per pound only, this would be equivalent o £150,000. Lastly, the alleged absolute certainty of a ample from one chest being a genuine sample of the whole reak, and thus obviating the possibility of the trade aving parcels of tea thrown on their hands on account of rregularity. This alleged certainty is, however, very eriously discounted by the possibility of teas being damaged by water or any other causes in transit, which night not be discovered until the teas were sold. This ast point, indeed, is the very one on which Mr. Lipton lays uch stress. Weighing the *pros* and *cons* of both systems carefully, the General Committee of the Indian Tea Association has strongly recommended that estate bulking should again come in force, and it behoves, therefore, the whole tea-planting community to loyally support their policy. It is one of the many little points in which the interests of producers clash with those of the brokers and middlemen, and it is to be sincerely hoped that victory will lie with the planters.

Roots as soil-tillers. In the December number of the *Journal of the R. A. S. E.* appeared an interesting paper by Mr. Robert Elliot, author of "Gold, Sport and Coffee in Mysore," on the value of plant roots as tillers of the soil. The direct interest possessed of the article for planters is not great, but there are one or two points worthy of attention. Mr. Elliot is nothing if not large-minded, and he claims to have solved the question that has been occupying the anxious thoughts of statesmen and scientists for the last three decades: how to enable the British farmer to successfully compete with his foreign rivals. He starts *ab ovo*, from the original fertility of virgin forest or virgin turf land. Such a soil is in perfect condition for the cultivation of crops, and its fertility depends on the length of time such mechanical condition is kept unimpaired. Plant food is of course indispensable, but unless facilities are given to the roots of plants to partake of that food, it is useless to heap the board with nutriment. He turns for confirmation of his views to coffee, where it is well known that the growth of the young plant is in direct ratio to the forest mould that covers the soil. "For, on comparing an analysis of the original soil with an analysis of soil from which sixteen crops of coffee had been taken without manure, we found the soil was little the worse, and only showed a slight deficiency in lime, the leaves which annually fall from the large trees which shade the coffee having evidently supplied the exhaustion caused by the crops. The examination was carefully conducted by the late Professor Anderson, of Glasgow, and a brother planter who called on him to hear the result very naturally asked how it was that, if the soil was only so slightly impaired, we could hardly grow young coffee in it, or but very unsuccessfully. Simply, replied the Professor, because the new soil is in a beautifully disintegrated, friable condition, while the old soil has lost that condition." With this as the groundwork for his argument, he proceeds to describe the results of repeated experiments in England in laying land down to grass and ploughing it up and cropping it at intervals. The pecuniary results of the system he claims to have been most gratifying. It seems a little strange that a "practical coffee-planter" should teach his scientific brother agriculturists in England the way how farming should be pursued. But practice has more than once shown science the way.

Fruit culture. The following article from the pages of the *Tropical Agriculturist* should be of interest to coffee-planters, especially to the exponents of the intensive system of culture on the Mysore plains:—

"On no account should the common custom be followed of bottoming every tree-planting hole with a shovelful of manure under the idea that the tree is getting thereby a special mark of attention. Independent of the fact that 'manure' too often means raw stable dung, fermenting fast and reeking with ammonia, there is this to be considered, that natural manurial agents can only be satisfactorily taken by the fine hair-roots when presented in a very dilute state

by the help of water. Moreover, the fermentation and decay of this organic matter gives off a large quantity of carbonic acid gas, filling up the interstices of the soil and driving upwards the atmospheric air which ought to fill them. Were it not that gases have a wonderful power of diffusion and dilute themselves away with great rapidity, the custom of bottoming tree-pits with fermenting dung would have been dropped long ago as a sure means of asphixiating the roots. If the soil is of average fertility and well prepared, or if being somewhat poorer, a little old well-rotted manure has been added during the trenching, there is not the least need for the manuring of the hole referred to.

"As a general statement it may be said that orchard manuring is best done by top dressing, and turning the material into the upper tilth to be carried slowly by solution down to the level of the roots. It is a good plan to have a plan of the orchard in which the rows are plotted and the individual trees have their names entered. This will enable one to identify each tree—as labels soon become illegible and no reliance can be placed upon a vague remembrance—distinguish the qualities of one from the other, and enable him to gain a general knowledge of fruit trees. If supports are necessary for transplants, the best plan is to put in two stakes 14 to 15 inches distant from the tree and tie it to a cross-bar fastened horizontally from one to the other: a single stake driven in among the roots is objectionable.

"When the trees have been firmly established, the condition of openness and aëration with free passages of moisture through it and away must be maintained.

"The whole of the ground between and among the trees has to be kept in an open worked condition, not only because it would otherwise harbour weeds which would draw sustenance from the soil which belongs to the trees, but for another and important reason. An open pulverulent tilth at the surface is the best preventive of evaporation from the underlayers in which the roots lie and perform their functions. As soon as a hard continuous surface-crust is formed, the uninterrupted capillary attraction exerted by the interstices of the soil-particles draws the moisture of the lower strata up to the heated crust, where it evaporates as fast as it is transmitted. It is not long, therefore, before the feeding-bed of the roots under such surface-crust is far too dry for their proper functions, the growth of the root hairs ceases, and the tree begins to show signs of flagging. Matters cannot be set right, as some ignorantly suppose, by flooding the root-bed with water. As the water gets slowly away by percolation, most of it is evaporated from the surface and the crust reproduced, with the inevitable result of the same capillary rising of the very water just administered and its dissipation into the air. There is, therefore, a pernicious alternation of a fast and feast forced upon the roots. The true remedy consists in interposing a loose powdery or fibrous stratum several inches thick between the layer of soil in which the roots live and perform their functions and the external air ever greedy of moisture. And there are two ways of doing this."

Some notes on rubber. Australia, as we are lately aware, is doing its best to encourage the cultivation of such varieties of rubber as are best suited to its climatic conditions. In an article in the *Sydney Mail*, a writer states that a successful introduction of suitable varieties might easily mean an additional million pounds sterling to New South Wales exports. There are varieties of rubber, which will only thrive in conc most unfavourable to human health, *i.e.*, great heat and moisture. As it is chiefly in those varieties that the r trade consisted until quite lately, it is not to be won at that up to the present experimental cultivation of r has been a failure, owing to the attempt to plant sw loving plants in ordinary soil. The wants of South I planters are identical with those of New South Wales the introduction of a variety that will thrive and pay existing plantation districts. There are a few Australian that yield rubber, but not in very encouraging quan The Castilloa has been tried in Ceylon, though the waiting inevitable before cropping has not been mu its favour. Experimental cultivation with this variet proved that shade is indispensable to the young p In planting up jungle with rubber, it is held to be lutely necessary to leave the scrub untouched for the few years, though the soil round the plant should be clean. Fifteen feet apart is said to be a good dis at which to plant them. The long delay in cro might be partially obviated by crushing the twigs and l at about the third or fourth year, the expressed juice fo very fair rubber. There is another variety, the Sa Biglandulosus, which forms quite an exception to all well-known sources of rubber: it grows at a high elev and, therefore, in a comparatively cool climate. Mr. Thompson, formerly in charge of the Jamaica Cin Plantations, now resides at Chapperel, Sante Fe de Bu Columbia, where since 1891 he has planted 70,000 se trees, which are doing well. It grows exceedingly ra and crops are obtained from the fifth or sixth The first yield is about 1 lb. per tree or 150 lbs acre, worth say 2*s.* 6*d.* per lb. Mr. Thompson's plant lying at an elevation between 6,000 ft. and 7,000 ft. the sea level, is land quite useless for other purposes so much success has attended his efforts that at Mon Rio Sinu, Mons. M. P. Durand has put in no less than 10 cuttings and seedlings, which are now flourishing. Thompson, so the *Kew Bulletin* reports, has offered Indian Government to deliver at the Nilgiris a large s of sapium plants and seeds insured to germinate for £1 Enquiries as to this tree are now being made by the p authorities in Sydney, and should the replies be satisfa no doubt an attempt will be made to acclimatise this We shall be glad to hear how the Indian Govern treats this important offer.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton:—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

LETTERS TO THE EDITOR.

TERRACING *vs.* DRAIN-CUTTING.

SIR,—With reference to the letters on the above subj your issues of the 5th and 19th February, and especia regard to "1 in 1's" objection about the space lost b natural slope of the ground between each terrace, I wr say that in Darjeeling, where the rainfall is as great as i South Indian planting district, and the soil, if anythi richer and more liable to wash, terraces two and more f depth have been maintained for years without any face and without any slopes or loss of space for them.

The secret of this, as pointed out in my first letter, is the evenness and flatness of the terraces preventing any c tion or concentration of drainage water which would be nece to do the scouring.

In regard to "1 in 1's" assumptions and argument about e slopes between terraces, I am unable to follow him, as he s assumed impossible conditions; for, in *any* hill, the slopes any) between terraces must always be greater, *i.e.*, steeper, an the slope of the hill, and can never be parallel to it.

Thus if 4-ft. terraces are cut with a 1 in 1 slope between ch pair, the slope of the hill in which they are cut cannot be eeper than 1 in 2, if the terraces are not less than 4 ft. above ch other; and if they are as much as 8 ft. above one another, e hill slope will still be only 2 in 3, *i.e.*, much less than in 1. Moreover, in every case, the hill will not require to be t into for more than half the width of the terrace, or 2 ft. ly and not four in this case. Of course, as stated by "Nemo," r wider terraces, the cutting and cost will be increased, but see no reason why they should be increased in width on e steeper hill slopes, where the trees of each terrace might e 6 ft. or any distance apart, and would be well above those the next lower one, with which they may be made to alternate so as to get more space, light and air.

And for the flatter hill slopes, the cost of an extra foot or wo in the width of each terrace would be comparatively very rifling. I must now leave the defence of "terracing" to my iends, for having many other pressing matters to attend to, am sorry I shall not be able to write any more on the subject.

ARCOT, } H. W. P.
nd March, 1898. }

GENERAL ARTICLES.

COCAINE MANUFACTURE IN INDIA.

WITH the view of increasing the cultivation of the coca plant—*Erythroxylon coca*—in India, the Curator of the Government Gardens n the Nilgiris has recently been requested by the Madras Government to obtain a supply of seeds annually, and offer for sale the lants rared therefrom. It is very satisfactory to note that, while he Madras Government is not prepared to engage actively in the anufacture of cocaine (the valuable alkaloid found in coca leaves), t is anxious to do all in its power to foster the cultivation of the lant in the Presidency.

It was introduced into Ceylon, from Kew, in 1870, and it is proable that the plants now cultivated in Madras came from the same ource. The suitability of the elevated lands in the Madras Presiency for the cultivation of coca has already been demonstrated in a eport by one of the Government Botanists, who, in addition, conidered that there should be no difficulty in extracting the pure lkaloid from the leaves in such a laboratory as that possessed by he Medical Stores Department. The report was issued in 1890, hen the price of cocaine hydrochloride was about 20*s.* per ounce, ut in view of the comparatively small quantity then required in the residency, where the annual consumption amounted to about three ounds, the Government was not prepared to institute any experiments in the direction indicated by an enquiry made by the Secretary f State for India as to the economic manufacture of cocaine ydrochloride in the country.

Three years later the experimental cultivation made at the Sikkim inchona Plantations proved a failure, and further attempts to raise he plant were abandoned. In 1894, however, the Madras Governent was again approached as to the advisability of instituting xperimental cultivation on the lower slopes of the Nilgiris, the ailure of the Sikkim crop being apparently due to the too great levation, as well as to the unsuitable climate of that plantation. he Government carefully considered the subject, but decided that he demand in India for the alkaloid was too small to justify anyhing beyond experimental cultivation. The latter was accordingly ommenced, and the results which are now to hand are eminently atisfactory. In the early part of this year the Collector and the hemical Examiner of the Nilgiri Gardens submitted further reports ealing with the expenses in growing the plant and extracting the lkaloid, and as the Madras Government is assured that the use of he drug has greatly increased, that the alkaloid can be readily extracted, and that the plant flourishes on the Nilgiris, it considers that it might, for some time to come, be profitable to private individuals to take up the cultivation of coca.

The enormous consumption of the alkaloid throughout the world may be judged by the fact that 22½ million pounds of dried leaf are produced annually in Peru and Bolivia. This represents about 55,000 lbs. of cocaine. It is owing, most probably, to the great increase in the exportation of the plant from South America, and its consequent cheapening in the European market, that coca cultivation has not materially developed in India. Two artificial substitutes are at present on the market, but it is not known how far they will supersede the natural alkaloid.

Although the employment of coca is almost entirely limited to medicine, there are indications that preparations of the drug, such as coca wine, are coming into use as a beverage, and as the Indian plant is particularly rich in alkaloid, both the active principle, if carefully prepared, and the raw leaves would find a ready sale in Europe.

There is, moreover, no reason why Indian cocaine should not find as ready a sale in European markets as the alkaloid from South America.

CARICA PAPAYA (LINN) N. O. PAPAYACEÆ.

Extract from "Drury's Useful Plants of India."

Papaw-tree, ENG.; Pappoia umbbalay marum, MAL.; Pepeya, BENG. and HIND.; Pappali-marum, TAM.

DESCRIPTION.—Tree, 20—30 feet, without branches; leaves alternate, palmate, 7-partite; segments oblong, acute, sinuated, the middle one 3 fid.; fruit succulent, oblong, furrowed: calyx small, 5 toothed; corolla tubular in the male and 5-lobed in the female, divided nearly to the base into 5 segments; male flowers axillary in slightly compound racemes or panicles, white female ones in short simple racemes, sometimes on a different tree; corolla longer than in the male, yellowish. Fl. July.—W. & A. Prod. i. 352.—Wight Ill. ii. t. 106, 107.—Lindl. Fl. Med. 107.—Papaya vulgaris, Lam.—P. carica, Goertin.—Rheede Mal. i. t. 15.—*Domesticated in India.*

MEDICAL USES.—This tree has several valuable medicinal properties. The milky juice is among the best vermifuges known. A single dose is sufficient for the cure. The natives in Travancore repeatedly use it for children. In the West Indies the powder of the seeds is used for the same purpose. The juice of the pulp of the fruit is used to destroy freckles on the skin caused by the sun's heat.—(Wight, Lindley.) Anthelmintic properties have also been assigned to the seeds. They are also believed among the natives to be powerfully emmenagogue.—*Pharm. of India.*

ECONOMIC USES.—This remarkable tree was introduced from America, but is now found in most parts of the Peninsula. The fruit grows to a tolerably large size, and secretes a milky viscid juice, which has the extraordinary property of hastening the decay of muscular fibre, when the latter is exposed to its influence. A great deal has been written upon the various effects which this secretion produces upon animal substances, and there appears to be little doubt that the juice really possesses the wonderful virtues attributed to it. I have attempted to collect the most important remarks which have been written upon this subject, as I find there is still a tendency among scientific men to doubt the very peculiar properties of the juice. Humboldt thus writes (Travels, ii., 52, Bohn's ed.) concerning it: "I may be permitted to add the result of some experiments which I attempted to make on the juice of the Carica papaya during my stay in the valleys of Aragua, though I was then almost destitute of chemical tests. The juice has been since examined by Vanquelin, and this celebrated chemist has very clearly recognised the albumen and caseous matter; he compares the milky sap to a substance strongly animalised—to the blood of animals.

"The younger the fruit of the Carica, the more milk it yields. It is even found in the germen scarcely fecundated. In proportion as the fruit ripens the milk becomes less abundant and more aqueous. When nitric acid, diluted with four parts of water, is added drop by drop to the milk expressed from a very young fruit, a very extraordinary phenomenon appears. At the centre of each drop a gelatinous pellicle is formed, divided by greyish streaks. These streaks are simply the juice rendered more aqueous, owing to the contact of the acid having deprived it of the albumen. At the same time the centre of the pellicles becomes opaque, and of the colour of the

yolk of an egg; they enlarge as if by the prolongation of divergent fibres. The whole liquid assumes at first the appearance of an agate with milk of clouds, and it seems as if organic membranes were forming under the eye of the observer. When the coagulum extends to the whole mass, the yellow spots again disappear. By agitation it becomes granular, like soft cheese. The yellow colour reappears on adding a few more drops of nitric acid. After a few hours the yellow colour turns to brown. The coagulum of the Papaw-tree, when newly prepared, being thrown into water, softens, dissolves in part, and gives a yellowish tint to the fluid. The milk, placed in contact with water only, forms also membranes. In an instant a tremulous jelly is precipitated resembling starch. This phenomenon is particularly striking if the water employed be heated to 40° or 60°. The jelly condenses in proportion as more water is poured upon it. It preserves a long time its whiteness, only growing yellow by the contact of a few drops of nitric acid."

Browne, in his "Natural History of Jamaica," p. 360, states that "water impregnated with the milky juice of this tree is thought to make all sorts of meat washed in it tender; but eight or ten minutes' steeping, it is said, will make it so soft that it will drop in pieces from the spit before it is well roasted, or turn soon to rags in the boiling." This circumstance has been repeatedly confirmed, and, moreover, that old hogs and old poultry, which are fed upon the leaves and fruit, however tough the meat they afford might otherwise be, is thus rendered perfectly tender, and good if eaten as soon as killed, but that the flesh passes very soon into a state of putridity. In the third volume of the Wernerian Society's Memoirs there is a highly interesting paper on the properties of the juice of the Papaw-tree by Dr. Holder, who witnessed its effects in the island of Barbadoes, and writes of them as known to all the inhabitants. The juice causes a separation of the muscular fibres. Nay, the very vapour of the tree serves this purpose; hence many people suspend the joints of meat, fowls, &c., in the upper part of the tree, in order to prepare them for the table. It is not known whether the power of hastening the decay of meat be attributable to the animal matter or fibrine contained in the juice of the papaw. The resemblance between the juice of the papaw-tree and animal matter is so close that one would be tempted to suspect some imposition, were not the evidence that it is really the juice of the tree quite unquestionable.

The tree grows very quickly, and bears fruit in three years from first putting down the seed. The fruit itself is pleasant to the taste, and is much relished in this country both by natives and Europeans. In order to render meat tender, either flesh or fowl, the simplest operation is to hang the flesh under the tree for two or three hours, which is quite sufficient. I have repeatedly tried it. Another way is to wrap the meat in the leaves and then to roast it. In a tropical climate like India, where meat requires to be cooked quickly, in order to provide against rapid decomposition (on which account it is often found very tough), there should be one of these trees in every garden. Wight mentions (Ill. ii. 36) that the farmers in the isle of Barbadoes mix the milky juice with water, and give to horses in order (to use their expression) "to break down the blood;" and this is a remarkable fact, that the effects of this dissolving power in the fruit is not confined to muscular fibre, but acts on the circulating blood. The negroes in the West Indies employ the leaves to wash linen instead of soap. The natives in India both pickle and preserve the fruit for their curries. It is very palatable even raw.—"Humboldt. Don. Wight. Lindley. Pers. Obs."—*Drury's Useful Plants of India.*

LIBERIAN IN THE STRAITS.

Weeding. ONE of the most important points to be observed by a planter, if not the most important, is the regular weeding of his clearing. To keep your estate free from weeds from the beginning is a very easy matter, but having once allowed it to get into a weedy state, it is a most difficult thing to get it clean again, and it will take about two years of regular weeding and will cost almost as much as opening a new clearing; indeed, it may often be advisable, instead of trying to put a neglected place to rights, to abandon it altogether and to open new land.

To keep an estate clean, you must start weeding immediately after burning the jungle and you must continue to do so regularly at once every month. A good many old and experienced planters a that it does no harm to have weeds; that on the contrary, in ground, it prevents the top soil from being washed away and the roots of the coffee from being exposed to the sun. Believe the planter who argues thus is either a fool himself, or he thinks you are one. I was of this way of thinking myself long ago, b never thought my listeners the fools; in my case, I was the ignor led into the mistake by advice given to me by men who sh have known better. It is rather a sorry joke to play on a y planter, and I don't see where the fun comes in in misleading a fellow who appeals to one for advice. And yet there are a numb people who delight in taking, what they are pleased to term, "a out of a new hand.

The weeds will absorb all the nourishment instead of the y coffee, and if allowed to grow up will suffocate it altogether; will also prevent the rain from penetrating the soil and reachin roots of the coffee.

If you could turf your estate carefully and keep the turf trim and short and the soil cleared and forked for about 2 feet all r each coffee tree, as has been done experimentally in some gar your coffee would no doubt greatly benefit; but this would be a difficult matter, and it would cost much more than weeding fact, it would never do on a coffee estate on a large scale.

The weeding, as I have already said, must be done regularly the very beginning at least once a month, the weeds must be t out with the roots and then be either burned or buried; never them lying about your clearing between the coffee; if you do, will grow up again in no time and be worse than before. If an e is clean, a woman will be able to weed from 200 to 400 trees in a but if your estate is under weeds, she will not be able to do than 10 to 20 trees. Thus 100 acres of coffee may be kept clea 6 to 12 coolies; but if once under weeds, you require from 33 t coolies to do it.

The result of neglect will not show itself on a coffee tree once; you may have your weeds growing a long time and not se bad effect, but when once the bad effect is seen, when your tree seedy and begin to fall off and to die out, then it will, in most be too late for remedial measures; no amount of weeding and m ing will then bring the tree back again to its former strong healthy condition, and even if your tree eventually recovers, i only be after a long course of careful nourishment and nursing any sign of improvement will be noticeable. Prevention in this again, is better than cure.

But should you by accident get your coffee into such a bad that the trees become bare and look as if they were dying, alth you have for a long time already been carefully nursing them, despair. As long as there is life there is hope, and very often, the trees are looking their worst, the experienced eye may dis signs of improvement and recovery. Let me compare such a with a man brought by fever to the very point of death: he has got over it and is on the path to recovery; he feels like a new child, and yet everybody who meets him will say, "Heavens, is the matter with you? You do look bad."

Let me now imagine that from one cause or another your e has got under weeds and that you wish to get it clean. This is

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

ne only in a systematic way: first, weed about 2 to 3 feet round e coffee trees to give them air and to prevent them from being ffocated; and, secondly, begin weeding your estate at one end and right on for 21 days. Weed as far as you can get within that ne, then begin again from the point where you first started. You ll get through it much quicker this time, perhaps in 14 days, is leaves you seven days more to go on weeding new ground, and on every time you will be able to weed more trees with the labour rce at your disposal, until at last you will be able to get right rough the whole of your estate within 21 days. Then is the time gradually decrease the number of coolies employed on weeding, ntil your clearing is again in a normal condition; then you can get rough your work with the ordinary number of coolies. But, let e tell you, this will take about two years.

My reason for advising you to weed once in 21 days is that most the weeds blossom within 21 days, and you must therefore weed efore that time, otherwise they will throw out new seed, which will e blown and scattered all over the estate, and the weeds instead of iminishing will spread more and more every time you attempt to estroy them.

Some planters may advise you to go right through with your eeding, even if it takes you two months to get round the first time. ach time you go round, they say, you will have less weeds and be ble to do it in less time; the second time you will probably be able o get through your weeding in one month. But if you follow this dvice you will never succeed in getting your estate clean again, nuch less be able to keep it clean.

upplying. Having planted out your trees, you must not imagine that you can be idle and wait uietly until they begin to bear. There are many things to do and o look after; of course you cannot do them all at once, so let us ake them one by one. First there is the "supplying." This means hat when a tree has died or does not grow to your satisfaction, it s replaced or supplied by another. After the first good shower of ain—or, rather, after every good shower—you put your men on to his work. Don't wait until you actually want to do the work, to ind out which trees want supplying, but do this beforehand. Examine each tree as you walk through the plantation, and wherever ou find a tree that wants supplying, mark it in some conspicuous ay, say, by putting in an *anakkayu*. You know then what you ave to do, and immediately after a good shower you are able to do t, without your coolies running all over the place with baskets full f young trees and changkols, hunting here and there for dead trees hich require supplying.

Very often a planter hesitates to replace a seedy-looking tree, hinking that with care and attentive nursing it may recover. This s misplaced sentimentality, although it is quite a natural human eeling, and I have given way to it myself more than once. In some ases I have had the satisfaction of seeing the tree recover, but in ost cases I have been disappointed. In a practical planter's life entiment is out of place: we are here to plant coffee with the disnct object in view of making it pay, and there is no doubt that it ays much better to replace a doubtful tree, by a fresh and healthy ne, than to try and improve it.

As I go on I find myself repeating the words, "this is of great nportance," and I have come to the conclusion that everything ith regard to coffee planting is of great importance, and I cannot lose this chapter without calling your attention again to the importnce of early and regular supplying.

The expenses of weeding, buildings, supervision, drains, etc., will e exactly the same for an acre of good and healthy trees as they ill be for an acre of seedy, half-starved or struggling-for-life iserable things; but whilst the former in course of time will give ou handsome returns and great satisfaction, the latter will always emain a source of heavy expenditure, without returns, but with nlimited worry, trouble and dissatisfaction. Now judge for yourelf, and say whether supplying is of importance or not.

Handling and pruning. A friend of mine once remarked: "Any fool can plant coffee and open an estate, but it is in the pruning and handling where the xperience of the planter shows itself." It is an art, and you must now what you are about. If you don't, you had better leave the tree lone, and probably much less harm will be done than by cutting off ny quantity of wood and branches which cannot be put on again. If eft to itself, the coffee will generally develop into a nice and regularly haped tree, and grow up to a height of 20 to 30 feet. But we do not llow our trees to grow so high; generally we top them when they are about 5 or 6 feet above the ground, just so high that a cooly can pick the berries without having to use a ladder. One might wonder why a tree should be cut off 5 feet above the ground when its natural habit is to grow up to 20 or 30. The reason is that when the tree grows up, the higher branches develop at the expense of the lower ones, whilst a tree topped 5 or 6 feet above the ground will shoot all its strength into the lower branches and make them spread over a much wider surface and bear more fruit than otherwise; then there is the advantage, as I have mentioned already, that you do not require ladders to pick your crop, which is a distinct advantage, for the use of them will always cause a certain amount of damage to the tree, however careful you may be.

Some planters believe in letting their trees grow up to any height, notwithstanding the above difficulties and the difficulty of handling and pruning such trees, and as marriage is a failure when it is a failure, so is a coffee tree a success when it is a success, and both ways—"the topping" as well as the "not topping"—have their advantages and their disadvantages; but where eminent men differ, I do not consider myself a competent judge to decide which of the two systems deserves preference.

Coffee is a plant which requires continual looking after; from the moment it is put into the nursery until the last day of its existence it must be attended to regularly every month. There is, for instance, the handling. As the coolies go along weeding they remove all suckers and dirt from the trees, bend the branches, and clean the stem from all parasites, ants, etc. Suckers are branches which grow upwards from the tree, and which would, if left alone, develop into another stem.

Then there is the pruning. But before I begin to describe the pruning, I must explain the different parts of the coffee-tree, or you will get bewildered about suckers, gormondisers, primaries, etc.

A tree consists of (1) the stem; (2) the branches growing out of the stem: under these I do not include the "suckers," which I have already explained, but branches growing out of the stem and spreading to the right and left of the tree and not growing upwards, these are called the "primaries"; (3) the branches, which grow out of the primaries, these are called "secondaries"; (4) of the branches which grow out of the secondaries, these are called "tertiaries"; and (5) the branches which grow upwards out of the above branches, these are called "gormondisers." Gormondisers, in the same way as suckers, will develop into individual trees and will take away the strength from the original tree, they nourish on it, and it accordingly suffers, and therefore all suckers and gormondisers are carefully cut off and not allowed to develop to any size.

The tree may have as many primaries and secondaries and tertiaries as nature will produce, but never allow any secondaries to grow out of a primary within a space of six inches from the stem, so that light and air can always penetrate right along the stem, and it has the additional advantage of rendering it easy for the cooly to examine the tree and to keep it clean. All dead wood is cut off the tree. Never allow more than one branch to grow out of the tree from one and the same spot: if there are two or three, remove the others and only leave the one which promises to turn out the best. All branches growing upwards and downwards and inwards instead of outwards are cut off.

This is the art of pruning, so far as I can explain it here. It is easy when you know it, but, etc.

Mr. J. Ferguson, in his "Coffee Planter's Manual" (third edition, Colombo: A. M. and J. Ferguson, 1894), among other remarks about pruning, writes: "Where a plantation has been carefully tended in its earlier years, where it has been properly and regularly handled, it will not, when it arrives at maturity, give much trouble in trimming; and except the cutting of dead wood, or wood that has borne (for the same wood never bears twice), removing suckers, cross branches, and exuberant shoots from the centre and along the primaries in the way hereafter explained, there will be very little to do in that line for some time. It is after an estate has borne two or three crops—after it has, either from overcutting or from want of timely handling, been allowed to get matted, umbrella-topped, or choked up by superfluous wood—that the real difficulty of pruning begins. It is now, too, that the planter's skill and science are called into play." And, later on, "I now come to what I consider the most important step in the pruning of the tree—the secondaries—because you have to deal with what is to give a great part of your next year's crop."

A writer, whom I have already quoted, "W," a well-known planter of great experience, in an able paper on Pruning, which he addressed

some years ago to the Planters' Association, describes this operation, and that of handling generally, so well that I take the liberty of giving his directions in his own words:—"To ensure a regular and strong tree, then, handling must be resorted to early. In doing so, take off all the branches that are within six inches of the stem, and make an opening of one foot in circumference in the centre of the tree. This, besides strengthening the primaries, will permit the sun and air to penetrate, both of which are beneficial to the growth of the tree as well as the ripening of crop. Next run along the primaries and single out the secondaries, leaving no pairs, but one secondary only at each joint, on either side of the primary alternately. This, I know, is thought very unnecessary by a large class of planters, but if they will only study the tree itself, they will find that although nature throws out the secondaries in pairs almost invariably one is stronger than the other; and by a little care the strong ones can be left and the weak ones taken off. It is better to look to the strength of the wood than the quantity of it. As secondaries left on too near the stem tend to weaken the primaries, so do they when left in pairs, cramping, as it were, that expansion which takes place under the treatment I advise."

DISTRICT ASSOCIATIONS.

KANAN DEVAN.

Quarterly General Meeting held at Munaar on 26th February 1898.

PRESENT:—Messrs. L. Davidson, P. Reed, T. W. Schmid, A. F. Martin, W. D. Martin, A. H. Mead, R. F. Russell, A. C. Williams, W. Milne, F. J. Graham, J. Hamilton Hunter, R. Hedger, H. M. Knight, A. H. Sharp (*Hon. Sec.*), A. W. L. Vernede (*Hon. Member*), and Mr. J. A. Rees (*British Resident*).

Mr. Knight was asked to take the chair.

Read and adopted minutes of last meeting.

Proposed by Mr. Davidson that Mr. J. A. Rees be invited to become an Honorary Member of the Association. Seconded by Mr. Knight and carried.

Roads and Communications.—Read letter from the President of the District Board, Madura, of the 24th December 1897, stating that, considering the difficulties represented by the planters, special provision had been made in the budget for 1898 and 1899 in addition to the ordinary maintenance allotment. Remetalling road from Periakulam to Thanee Rs. 2,000. Remetalling road from Periakulam to Batlagundu Rs. 1,500. The maintenance allotment for the road from Thanee to Bodinaickanur has besides been raised from Rs. 100 to Rs. 200 per mile. Regarding the question of raising the maintenance allotment of the Devikulam ghat road, the District Board Engineer has promised to shortly inspect the road and submit his recommendations to the President, District Board. Recorded with satisfaction.

It was proposed from the chair and carried that a vote of thanks be accorded to the District Board.

Read copy of the report of the estimate for a road between Pallapallayam and the Chinnar river. Proposed by Mr. Davidson and seconded by Mr. Sharp that this report be referred to a Sub-Committee, Messrs. A. F. Martin, W. Milne, J. Payne, and the Honorary Secretary to consider and reply to the same. Carried.

Read letter from the Secretary, Public Works Department, of 11th January 1898, having reference to connecting the Periakulam-Munaar road with the proposed new line of communication through the Annamallai Hills. Read the Honorary Secretary's reply. Recorded.

The Honorary Secretary stated that he had on the 25th January 1898 again written to the Dewan, urging Government to take over the maintenance of the district outlet road between Munaar and the Mettu, and he has been informed that the matter had been referred to the Chief Engineer. Recorded.

Mr. Davidson informed the meeting of what Messrs. Finlay, Muir and Co., as representing the Kanan Devan Hills Produce Co., Ld., had been doing in regard to this matter, and stated he now understood that the British Government intended to at once commence work on the Udumalapet-Chinnar road, and that he hoped they would ultimately see good cart road communication between that town and Talliar. He also stated that he had been informed that the British Government intended to provide funds for repairing the present road from Thanee through Bodinaickanur to the foot of Kotagudi ghat and to push forward this work as rapidly as possible.

The present position in regard to the western outlet to Cochin was also explained by Mr. Davidson.

It was proposed by Mr. Hedger that Messrs. Finlay, Muir an be thanked by the Association for the trouble they were taki regard to these road matters, and that as they were in communi with the British and Travancore Governments, the Association s have in their hands all correspondence in connection with roads for this district. Seconded by Mr. W. D. Martin and ca

Arrack Shops.—Read letter from Messrs. Milne and Arms deprecating the erection of arrack shops throughout the di Proposed by Mr. Davidson and seconded by Mr. Sharp that the Association has no desire to prevent the reasonable establish of arrack taverns, the Secretary be instructed to write t magistrate with a view to his securing the Association co-oper in the matter of properly regulating the sale of liquor genera natives and the proper location of arrack taverns, or the suppre of them in the event of their becoming a menace to the peace community or injurious to the natives themselves. Carried.

Dilatoriness of the Police.—The Honorary Secretary state he had received a letter from the Superintendent of Police, date December 1897, asking for the names and numbers of the referred to at last meeting. These had been accorded to him, b further reply had been received. Mr. Vernede then stated th knew the Superintendent of Police was acting in the matter. Honorary Secretary then stated that the number of fraudulent yali contractors was largely increasing, and he believed that thi mainly due to the ease with which they were able to avoid war presumably by bribing the police.

Game Reservation.—The Honorary Secretary stated t neighbouring portion of the Cardamom Hills had lately been p under reserve, and he had reason to believe that it was to be tended as to practically prevent the planters from shooting any on the Cardamom Hills. As every one he had spoken to was u mous on the subject, he had written to the Dewan pointing out such action would come hard on men who by their calling obliged to live in the jungles. The Honorary Secretary pro the following resolution, viz., that a gun license should inste established to prevent the indiscriminate slaughter of game. resolution was withdrawn on the Chairman pointing out that a license was procurable from Government.

Telegraphs.—Read letter from the Director-General of Teleg of 15th February 1898, to Messrs. Finlay, Muir and Co., Cal stating that the telegraph line could be extended to Munaa guarantee of Rs. 1,640 per annum for a minimum period of five renewable, if required, for a further period, the terms of the guar being that if the departmental share of the receipts from mes booked at Munaar fails in any one year to reach the annual s Rs. 1,640, the difference for that year is to be paid to the Tele Department. The account being closed annually, should receipts exceed Rs. 1,640 in any year, the excess to accrue Government.

Read letter from Messrs. Finlay, Muir and Co., dated 16th Feb 1898, stating that to save time they had given the necessary guar which they asked the Association to accept.

Proposed from the chair that Messrs. Finlay, Muir and C written to accepting the guarantee on condition that Mr. A. K. uses his best influence to have the line connected with the kulam Post Office and that Mr. Muir be thanked for his trou the matter. Carried.

Bodinaickanur Store and Rest-House.—Read letter from M Muir, making the following proposals, viz., that it would be convenient to build the new bungalow and store two or three further out from Bodi and towards the ghats, and that they wou prepared to discuss with the Association what they would charg looking after their interests.

Proposed by Mr. Knight that the offer made by Messrs. F Muir and Co. be accepted with thanks. That is, that the As tion takes up a new piece of land at a suitable place and buil bungalow there and a new store, Messrs. Finlay, Muir an undertaking to run the establishment at a cost not to exceed tw on every 10lb. gross weight passing through the store. Second Mr. Hedger and carried.

The following Sub-Committee was appointed to select and s the land, viz., Messrs. Sharp, Davidson and Knight.

Mr. Knight in a short speech thanked the British Reside having kindly atttended the meeting.

The meeting closed with a vote of thanks to the chair.

A. H. SHARP, *Honorary Secreta*

NILGIRIS.

PROCEEDINGS of a General Meeting of the Nilgiri Planters' Association, held at the Masonic Hall, Ootacamund, on February 5th, 1898.

PRESENT:—Messrs. R. James, D. Cockburn, H D. Wilbraham, J. Hardy Pascoe, B. A. Marden, L. W. Grey, H. Barber, J. W. Minchin, and G. Windle, *Honorary Secretary*.

Mr. Rhodes James was elected to the chair.

1. Proceedings of last meeting were taken as read.

2. The Honorary Secretary reported that in consequence of the lack of support from other Associations, the idea of a joint Agricultural Chemist must be given up. There was some talk, however, amongst individual planters, of a few subscribing, possibly in conjunction with a firm, to procure a private chemist. The amount which the members of the N.P.A. had been willing to subscribe to a general fund was Rs.2,100 for a term of years.

3. *Lady-bird Fund.*—Read letter from the Hon. Mr. H.P. Hodgson, dated January 28th, enclosing copy of the Proceedings of the Madras Government, dated January 17th, stating that Rs.2,000 would be contributed towards Mr. Newport's expenses in procuring and importing lady-birds, and requesting the Accountant-General to place an advance of Rs.1,000 at Mr. Newport's disposal. Also read letter from Mr. Newport, dated January 27th, to the Honorary Secretary, U.P.A. With reference to this latter, the Association considered that Mr. Newport should bring the lady-birds with him, but could give no opinion as to what arrangements he should make for their subsequent despatch. It was considered advisable for his headquarters to be on the Lower Pulneys on his return, on the score of expense and the greater virulence of the green bug on the Lower Pulneys. The Honorary Secretary, in compliance with the suggestion of the Chairman, U.P.A.S.I., will correspond with the Hony. Secy., Lower Pulneys Planters' Association. The amount subscribed by the N. P. A. and forwarded to the Secretary, U.P.A.S.I., was Rs.2,125; the Government of Madras has given Rs.2,000, U.P.A.S.I. Rs.2,000, and the Lower Pulneys P.A. promised not less than Rs.4,000, which would make a total of some Rs.10,000 available, if necessary, for the experiment.

4. The Hony. Secretary stated that he had paid Mr. Kenworthy Brown's fee, Rs.52/8, for his opinion on the contract forms applicable to Act XIII. of 1859, but that the opinion had not yet arrived.

5. The Superintendent of Police, Coimbatore, has placed a guard at Nellathorai during the coffee season. There having been complaints on the part of the police as to incomplete coffee passes, a specimen form, forwarded by the police, was shown to the members present.

6. Proposed by Mr. L.W. Grey, seconded by Mr. W. Rhodes James, that the Hon. Mr. H. P. Hodgson be again nominated as Planting Member at the expiration of his present period of office. Carried unanimously.

7. Mr. E. R. Kindersley's proposition was referred to the Planting Member for his opinion.

8. Criminal Procedure Code—Recorded.

A vote of thanks to the Chairman closed the proceedings.

W. RHODES JAMES, *Chairman.*
E. G. WINDLE, *Honorary Secretary.*

TO STAMP COLLECTORS.

5,00,000 Foreign Stamps, (well-mixed,)

Includes some very good varieties. The best offered at the price, which is extremely low.

No. 1a. Containing 100 Stamps, Rs. 1-4 (post free).

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (February 18, 1898) says:—The supplies brought forward in Public Sale this week met a steady demand, good and superior descriptions being easily disposed of at full values.

Only one mark East India was offered, but this realised extreme rates.

Guatemala, of which the catalogues chiefly consisted, attracted fair competition, and fine colory qualities fetched very firm prices, but the common kinds sold slowly at irregular and easier values.

Futures have been rather firmer this week owing to a slight falling off in receipts, and the market closes 9d dearer than our last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending February 16th, 1898, says:—Bank rate 3%. Bombay Exchange closes at 1s. 3⅞d. Brazil Exchange 6¾d. Rupee paper 3½% 63⅝. Silver 25⅞d. per oz.

The moderate supplies at auction went off about steadily, prices at the close shewing no change; colory kinds continue to meet with good competition, ordinary and common being again dull and somewhat lower. Brazil markets are unchanged.

Daily receipts averaged 11,000 bags in Rio, and 11,500 bags in Santos.

Futures have ruled quiet, but at the close a decided advance has taken place of about 9d to 1s 3d per cwt., viz.:—Good average Santos in Havre, March delivery, fcs. 37.00, in Hamburg pf. 30½, and No. 7 low ordinary Rio in New York $5.75.

To-day's London official quotations are:—

	Feb.	March	May	July	Sept.	Dec., '98.
SANTOS ...	30/-	30/3	30/9	31/-	31/6	32/-

Indian. Another week of small auctions has added strength to the market, an improved tone being shown for all descriptions, and prices generally marking a distinct advance. The Official Wire gives exports to U. K. from 1st April to the middle of the month, as lbs. 132,420,000 against lbs. 130,460,000 for same date last season, and shipments for first half of month as lbs. 1,970,000, against lbs. 2,820,000 last year. A fine invoice from "Suddia Road" averaged 1/9 per lb. and included a small lot of B. O. P. which brought 4/2½.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c. Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 25th March, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Coorg.

POLLI BETTA, 15*th March.—Weather.*—A blazing sun and high east wind have been the order of the day since last report. Not a sign of rain. *Crops.*—Spike keeping fresh and healthy, but a good downpour is wanted early. *Public Health.*—A wave of sickness seems to be passing over the place. A regular epidemic of bronchitis and fevers appears to be prevailing in parts. Or is it influenza? Estates are paying off.

S. E. Wynaad.

DEVALA, 16*th March.—Weather.*—Since my last report the wind is still blowing strongly, not constantly but at intervals both by day and night. As soon as the wind stops, it is very hot and unbearable by day and night. *Crops.*—The spikes are still lingering from want of rain in the open, but in the shade the blossom is set and looks very healthy.

Nilgiris.

KULLAKAMBY, 17*th March.—Weather.*—Strong east wind and bright sunshine. No signs of rain. *Crops.*—Coffee crop practically over; good healthy spike and fair promise for next year's crop, if rain does not fail. Pruning and manuring in full swing. Prices of grain going down. *Health.*—Fair. *Labour.*—Plentiful.

Kadur.

MUDIGERE, 15*th March.—Weather.*—The east wind has been very strong, lasting quite four hours a day. 30 cents of rain were registered on one or two estates on 4th, which has brought out the blossom. Luckily the shower was very local. Rain now would be welcome. *Health.*—A few cases of cholera in Mudigere and small-pox has appeared in Chickmaglur. *Interesting items.*—The Volunteer Camp of Exercise takes place at *Saklaspur* from 5th to 9th, when a large attendance is expected. Another well-known planter

has passed away. Mr. McMaster died at Sumpsi last week He was for many years at Tuttapollium and was well known on the Nilgiris. It is good news to hear that the Dewan has asked the local Association to report upon the introduction of a Game Act, and a sub-committee has been formed to draw up a reply. A Game Act and a Wild Birds Protection Act would be welcomed by the many sportsmen in the district.

THE MERCANTILE ASPECT OF THE CURRENCY QUESTION.

It is always well to be acquainted with both sides of a question, however firmly convinced one may be of the overwhelming truth of the particular side one supports. Our readers have heard a good deal lately, both in this paper and in our Madras contemporaries, of the way in which producers view the problem. We therefore make no apology for attempting to summarise, as clearly and impartially as may be, the arguments used by a very influential majority of the trading firms of the country. For that purpose we shall avail ourselves of the annual address lately delivered to the Calcutta Chamber of Commerce by the President of that body.

The wisdom of the action of Government in refusing to join America and France to remonetize silver was universally recognized, in view of the disastrous consequences of the very sudden rise in the rupee from 1*s.* 5*d.* in January 1890 to 1*s.* $8\frac{13}{16}d.$ in August. The rapid and great fall that then took place averted a most terrible disaster. But, says the President, it is not so easy to share in the sanguine view held by Government, with regard to the present currency policy, which is causing such injury to trade. Until the gold standard scheme is made effective, he continues, Indian trade will continue to be hampered by sudden and violent exchange fluctuations. The alternative is to reopen the mints, but the present insecurity of sterling capital invested in India will be then incomparably greater. Some people hold that with open mints, the rupee would be fairly stable at between 1*s.* 1*d.* and 1*s.* 2*d.* But if it was impossible to prevent the steady depreciation of the international value of silver, when America was buying fifty-four millions of ounces yearly, and other countries were also buyers, how would it be possible to prevent this when India remains practically the only large buyer? He condemns very strongly the use of silver as a standard, as the metal will in time be practically unsaleable outside India, and stability of exchange with the outside world impossible. Within a month of the mints being reopened, the rupee would fall to 11*d.*, and could not rise above that so long as the present ratio between gold and silver coins prevails in Japan. In that country the gold and silver yen are interchangeable.

"The gold yen, if shipped to London, and minted, would outturn 2*s.* $0\frac{9}{32}d.$ The silver yen, if minted in India under the old conditions, would outturn a little under Rs.222 per 100 silver yens. The Exchange Banks could sell sterling in Japan at about 2*s.* $0\frac{1}{3}d.$, and could buy and ship to India silver yens which, if minted in India, would, as I have said, outturn Rs.222 per 100 silver yens, which is equal to about 11*d.* per rupee. The transaction would pay the banks so long as Indian exchange remained a fraction above 11*d.* It is therefore plain that the rupee could not rise above 11*d.* without being immediately arrested by shipments of yens; and this would last until Japan was denuded of yens, or until silver was maintained at a level above 29*d.* Under these circumstances the maximum rate for the rupee in India would be 11*d.* unless silver rose above ? per oz., with absolutely no certainty that it might not fall to or 6*d.*"

Eighty per cent. of India's whole trade is with gold-us countries; the countries of the world have declared gold; India should cast in her lot with them. Amer still has great hopes of inducing India, with the aid their powerful bimetallic allies in the British Cabinet, accept her scheme of remonetizing silver. This mean 1*s.* 11*d.* rupee, disastrous to the whole trade of the count as well as to all producers. The Government of India ha declared for a 1*s.* 4*d.* rupee. Of the two proposals, latter is obviously the only one to be even thought of. T alternative is the reopening of the mints, which means the mercantile community, either the immediate bankrup of the Government, or such a sudden and great rise taxation as would in all probability lead to another muti

We cannot refrain from pointing out how utterly familiar to the public outside of Madras, is the U. P. A. S scheme of imposing automatic export duties on a slid scale, rising or falling according to the current exchan No loss of revenue would ensue to Government, and con quently additional taxation need not be dreamt of.

To return to the arguments of the other side.

With an 11*d.* rupee, all sterling companies in Ind whose capital is exchanged at 1*s.* 4*d.*, would have im diately to write off a third of their capital. With a fi exchange capital would flow largely into the country a her agriculture and industrial resources would be en mously developed. The position in America at the pres day is worthy of notice. The threat of silver legislat prior to the last Presidential election, effected what great financial panic in July 1893 was unable to acco plish: the almost entire cessation of the usual credit fa lities, and such a withdrawal of English capital as has back the trade of the country to an enormous extent.

The present position is intolerable, and early and decis action is urgently required.

Such, in brief, are the most notable arguments advan by the President of the Calcutta Chamber of Comme in supporting the gold standard policy of Government. may be we have slurred over some, and omitted oth If so, it has been unintentional. Yet as they stand abo and if nothing stronger can be urged in support of a fi 1*s.* 4*d.* rupee, the adherents of an "honest" rupee n well take heart.

We had not meant here to offer any criticisms of own, but a few words may not be out of place. Produc cannot expect in any case to have things exactly as t wish them. They must give and take. Their scheme sliding scale of export duties will render the free coin of silver an easy matter. But it will not, as far as we aware, tend to obviate those very fluctuations in exchan which are the despair of the trade. Such stability can o be obtained by artificial means, *i.e.*, by Government fix the exchange value of the rupee by means of a gold dep in England. For the present, producers would proba feel more than content with an exchange of say 11*d.* to to bring it into comparatively close connection with value of silver. Yet in a few years it is probable that standard will fall lower still, apparently necessitating, f the producer's point of view, a fresh alteration of the fi exchange.

NOTES.

ssia in Ceylon.

A branch of the Russian Tea Firm, Messrs. Mochanoff, Peehatnoff Co., was lately opened in Colombo by Mr. Frank lkwill. A Russian Manager is expected to arrive in a tnight. This firm has for some time past been doing a ge trade in Ceylon tea by purchasing in London.

new transplanter.

Mr. George W. Claridge, a North Travancore planter, has patented an proved style of transplanter, which he claims to be perior to all other devices of the kind. The Indian ents are the Mercantile Mission Branch of Calicut. It is of urse impossible to pass an opinion on the invention with- t actual trial, but various advantages are claimed, such simplicity, thoroughness of work, roots not being dis- rbed, &c., &c. On receipt of six annas in stamps the gent will forward samples.

e American Tea Campaign.

In Mr. Bleckynden's annual report for 1897 to the London branch of the Indian Tea Association we te that about two-thirds of the total expenditure in shing Indian and Ceylon teas in America is devoted to vertisements. The consumption of British-grown teas in orth America increased by about 54 per cent. in two ars, against decreases varying from 13 to 53 per cent. in ner teas. The revised American customs regulations have d a marked effect in shutting out China and Japan teas.

anipuri Hill tea.

Mr. R. C. Wright, a Ceylon planter, has just returned from a narkable tramp through the Shan States in quest of the oure and unadulterated" Manipuri seed. He found the easily enough, but unluckily mistimed his visit, arriving the blossoming instead of the crop season. It was nd Nassam, the capital of the Taungbaing State, that best tea is grown. Nassam is 5,000 feet above the sea. is tea is the wild tea of Burmah, but round Nassam, and other places, it is largely, though rudely, cultivated and leaves manufactured into pickled or "leppet" tea. e travelling was exceedingly rough, but the natives d and inoffensive, very different from the Kachin tribes.

w plantation staples.

Para rubber is being very extensively planted up in Ceylon. Of the 100,000 seed raised at the Botanic rdens, over 25,000 were sold to planters in the island, ile the demand has been enormously over the supply. *mphor* trees are doing well at Hakgala, some being 9 t high, while of those distributed in 1895 in Galle some ve reached 12 feet. *Vanilla* and *Ipecacuanha* are both racting attention in Ceylon. We may mention that the ter is being experimented with on the Annamalais, with nts obtained from the Burliar (Nilgiris) Experimental rden. Ipecacuanha is a tiny shrub of a few inches in ight. Its root matures in a couple of years, when it ay be broken off and the stem replanted. Propagation easily effected by leaf cuttings. A warm, moist and eltered position is requisite, while shade is indispensable their well-being. They are planted a few inches apart. e market value of the crop of an acre of well-grown ecacuanha runs into close upon four figures. The initial cost of stocking and plantation, if done on a large scale, is of course enormous.

Depreciation in Ceylon tea shares.

The *Times of Ceylon*, never, it must be noted, of an over-sanguine temperament, draws a woful picture of the present state of both sterling and rupee produce companies of the island, as compared to the inflated period of 1895. Our contemporary writes:—"It is a very disappointing statement which we have to make: but not to face the situation would in no wise improve it, and it is better to regard things exactly as they are. The record of losses during 1897 on local quotations—accentuated this year to the present date—when reckoned on all the existing scrip, assumes astounding proportions; and use must be made of it to show the home authorities how adverse conditions have combined to check our prosperity—the prosperity at present, principally, of the European community in Ceylon. Its reflex action upon the island generally has not become very manifest yet, but must already be bringing its influence to bear in many directions." While the lower prices for last year certainly have a good deal to say to the critical position of affairs, it is beyond all question that exchange has had a greater effect. The net depreciation since 1st January 1897 in the shares of some fifty odd rupee companies is put at the astounding total of Rs.58,00,522. The present quotations, Rs.1,57,52,150, are, however, still higher than the par values of the scrip, which is Rs.1,49,20,040.

Prospects of Liberian coffee.

Your leading article upon Liberian coffee, writes the London correspondent of an exchange, sent me this week to the office of a firm of brokers who dispose of a good quantity of this product. The object of my visit was to put a few straight questions regarding the great fall in price from the time when Ceylon Liberian coffee was only 10*s.* per cwt. in price behind, middling plantation Ceylon realising 90*s.* against 100*s.* for Coffee Arabica. Upon the tables in the sample room were a number of samples of parcels on sale that day. It was evident from the cursory glance given by some of the buyers, who dropped in and out to view the samples, and their rapid disappearance, that there were not a great number of bids to be relied on. I paid more attention to what was displayed and I made the Borneo samples considerably better than those from Ceylon. The head of the firm in response to my enquiries thus briefly put the case. When Liberian coffee was fetching 90*s.* it was a novelty. And its best point was that when *roasted* it turned out a splendid appearance for shop windows. But it has been tried and found wanting in its capacity to please the palates of English consumers. It is seldom we get any that is not unpleasant in flavour. No Liberian coffee has thoroughly pleased buyers. When the coffee is grown in Liberia it is most unpleasant in the cup, and it has been only very slightly improved in flavour by transplantation, although much in appearance. The last named coffee is only fetching 28*s.* per cwt. Ceylon is fetching 35*s.* to 40*s.* But, said the broker, you can buy Santos coffee 30*s.* to 40*s.*, which although sometimes a little earthy is certainly in many cases far more suitable for English requirements than Ceylon Liberian. They have got as near perfection as is

possible in Ceylon, but my opinion is it will never be popular. Thus the broker, and that is the latest up-to-date report on the prospects of Liberian coffee on this side.

The Produce Market. Supplies continue to come forward in small quantities, reports the *Produce Market Review* of 19th ultimo, and, in fact, they are hardly sufficient to test the market. At this time of year the auctions are, as a rule, heavier than can be got through in the day, but now they are lighter than is often the case in the autumn. Advices of larger shipments have, however, now been received, and a better supply may be looked for during the next fortnight or so. Prices continue to show the same irregularity; the few fine lots offered have fetched quite as high prices, while medium and common have been difficult of sale, as importers were not prepared to take any reduction. Rather larger supplies of new crop Guatemala have been offered, and were freely taken for the export trade. Mocha continues dull of sale, and in plentiful supply, excepting fine transparent, which is exceptionally scarce. In the terminal market there has been a slight advance, owing to a falling off in the daily receipts, and heavy buying in Brazil which has caused a rise in the prices there.

Indian Teas.—The market has been fairly steady, the quantity brought forward not being in excess of requirements. The principal movement is in the finest grades, which are actively competed for at advancing prices. There appears to be little doubt that these descriptions, as is often the case towards the end of the season, will be in moderate supply in a month or two, and this has stimulated buyers to secure stocks while available. As we have previously pointed out, there is likely to be a deficiency in the crop of Assams, and as these teas have on the whole been uniformly the most desirable growths of the season, it will not be surprising if there is a general upward movement in their value before long. That there will be plenty of tea to meet the consumption is quite probable, but there is no doubt that the increase in the stock mainly consists of growths which throughout the season have for the most part been of poor quality, and which will continue to be comparatively neglected so long as the more useful sorts can be obtained at reasonable prices. There was a fairly good assortment offered at the public sales, which comprised 30,825 packages, and there was the same active bidding which characterised the sales for Assams and some of the Dooars growths for the past few weeks, while in most cases prices showed considerable firmness, and occasional advances were paid. The lower kinds sold irregularly, and those giving a poor infusion declined in value.

How water enters the soil. In an interesting paper entitled "Reasons for Cultivating the Soil," Mr. Milton Whitney, Chief of the Division of Agricultural Soils, V. S. Department of Agriculture, the author describes how water enters the soil, and its importance in plant economy. It is the most abundant substance found in living crops. On account of evaporation from the leaves, about thirty to forty times more water is needed in the growing period of the crop than is contained in harvested crop. The maintenance of a proper water-supply is therefore one of the most important functions of the soil. If the soil is loose and sandy, its granules are large and rain water soon s between out of the reach of the plants. Clayey soi the contrary has its granules very finely divided, consequently very close together. This results in downward movement of the water being very s Cultivation can do a great deal to assist or combat natural qualities of any soil. But the style of cultiva must be suited to the class of plant. Turning to staples, it is obvious that as a rule it is desirabl conserve all the moisture possible for tea, while it is the opposite with coffee, notably at the "winteri period. Besides the loss through transpiration of the lea water escapes from the soil itself either at weeds or d from the surface. *Ergo,* keep your estates perfectly from weeds in times of drought. A loose stirring of surface soil will kill weeds, and prevent surface evap tion. The principal uses of initial cultivation is to lo the soil to enable it to retain rainfall more fully. Secon to maintain that rainfall near the roots of pla Thirdly and fourthly, to admit fresh air to the roots, to enable them to penetrate the soil more easily. Subseq cultivation is chiefly to prevent loss of water by weeds grass, which use up great quantities; to keep the sur covered with a loose dry mulch to prevent sur evaporation.

If theoretical conclusions may be drawn from the ab we would suggest that deep cultivation for tea shoul undertaken just before, and during, the monsoon. S sequent cultivation should be shallow and continuous. V coffee, deep cultivation might be necessary about Jan to induce "wintering." When the blossom is set, l cultivation would conserve the moisture requisite to s the young berry. Deep cultivation just before the so west monsoon should be avoided, and the growth of w encouraged within a reasonable extent. Subsequent cul tion to be shallow and often, according to the mois required.

A soil with a compact surface quickly dries out, and water-supply fluctuates rapidly and excessively, to detriment of most crops during their growing pe Weeds are generally to be excluded from the crop bec of the water they use up. But, says Mr. Whitney, are occasionally of use to the crops, especially during ripening period, because they help to dry out the soil thus hasten the maturity of the crop.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain ton:—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed the parent trees of above analysis at Rs.6 per pound conta about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere from the

MANAGER, ARIENKOW ESTATE,

LETTERS TO THE EDITOR.

E. LITHOSPERMA SHADE COFFEE.

SIR,—As so many planters are interested in growing *E. Lithosma* as an aid to coffee fertility, they may be glad to know that the old coffee under that shade has blossomed magnificently, and, what is more important, has set the blossom; cwts. an acre may, I think, be fairly expected, and it is the more remarkable as all other coffee (other than *E. L.* shade) has done rather worse than usual. The fine show on the *E. L.* coffee has been obtained by a rather novel method of treating the shade trees which I hope to describe in detail at some future date; but in the meantime I shall be glad to show the coffee to any planter who cares to see it.

RIENKOW, SHENCOTTAH,
11*th March*, 1898. B. NELSON.

DRAINS AND TEA-PRUNINGS.

SIR,—In going over a neighbouring estate the other day, I was struck with the way in which the prunings were disposed of. Shallow 6-inch trenches were dug *down* the face of the hill, the earth from which were spread over the prunings, which were of course very "light." This reminded me of what occurred to me this year, and by accident some drains were left full of tea-prunings, and heavy rains ensuing, made me go round to inspect what I thought to be the awful state of wash resulting from burst drains. To my surprise, they had kept perfectly open, all silt, rubbish, &c., falling into them from above, were held by the interlacing twigs of the prunings, affording a perfect waterway beneath.

A neighbouring field, which had its drains kept clear of all prunings in the orthodox way, suffered a great deal from blocked drains, affording a striking contrast. Then I remembered that a Ceylon planter had tried the very same thing, which was noticed in your paper a month or two ago.

I have always taken a keen interest in the subject of draining, but this result astonished me not a little. I intend carrying it out thoroughly this year, with alternate drains to compare the differences. There is one precaution, and an essential one, to be taken: the prunings should be laid as thickly and evenly as possible (they may stand at least a foot or so above the level of the upper bank) *from end to end of the drain*. If there are gaps in the system, the drain will be liable to burst at that point.

ECKSYZED.

WEEDING OF TEA ESTATES.

SIR,—In these days of small profits and high exchange, it seems to me that every attention should be paid to small economies in the field and factory. A rupee saved per acre on weeding, say, or cultivation, picking, pruning and what not, mount up to a goodly sum at the end of the season. There are generally speaking two principal styles of weeding in South India; mamoty scraping and handweeding, supplemented by such works of cultivation as digging, forking and trenching. Being short of coolies, and the totes being very dirty, I tried mamoty scraping as the quickest way to get the place fairly clean again. It acted beautifully at first, the grass and other weeds dried up and died out almost completely. I intended to follow this up with a forking to mitigate the inevitable wash of the loose surface soil that I dreaded. Unluckily heavy rains occurred before my forking was even commenced, and the results in wash were something horrid. Drains blocked and burst, and the land cleared of almost every bit of surface soil disturbed in the mamoty-scraping.

Cheap the operation was in one way, but very nasty and expensive in another. Being still short of labour, and anxious to clean up the tote thoroughly, I have been recently experimenting with the Assam fork, which is at right angles to the handle and used like a mamoty. This I find to be extremely satisfactory in all ways. The pattern I use is the 4-pronged one, which can, I believe, be obtained from Madras (Leighton & Co.); I don't think the other local firms supply it. The mere weight of the fork drives it into hard soil about four inches or so, and an easy pull brings the clod of earth forward, reversing it completely. It is in fact a very cheap form of "clean digging." The first forking costs me 3 rupees per acre, two succeeding ones only 2 rupees, total 7 rupees for the year. Add one thorough hand-weeding in the year at 5 rupees, total for weeding and cultivation 12 rupees, which is the usual cost for hand-weeding. Hand-weeding, however, entails extra cost for cultivation, which if similar to that given above, only done with the ordinary fork, will cost quite 10 rupees if not 12. Ten rupees per acre saved is no small thing. It is possible that as good work could be done with the Assam "kodallie grubber," which is a smaller edition of the quintanie. The ordinary mamoty is both too broad and too light to dig in hard land, unless at a great cost.

"ASSAM FORK."

AGRICULTURAL SCIENCE.

SIR,—I have read with interest the letter of "Erin Gobra" which appeared in *Planting Opinion* of the 5th March, and as in that issue you expressed a regret that you had not received more communications on the subject of scientific manuring, I venture, although an inexperienced planter, to address you on the subject.

From the reports that have appeared from time to time of the District Association Meetings, it appears that, with one or two exceptions, practically the whole of the planting industry of Southern India has rejected the proposal made at the last U. P. A. Meeting of securing the services of an agricultural expert.

Now it seems to me that there may be two reasons why planters should vote against this proposal. They might do so on the ground of expense, or they might urge that they have no faith in agricultural science.

Those who have been influenced by the former reason appear at first sight to have had some grounds for their decision. For in years like the last two or three, at any rate in this district, one certainly cannot afford to throw away an anna. But I maintain that even if scientific advice should not reveal the art of obtaining better crops, it would at least save us from enormous waste. When one considers the thousands of pounds that are yearly spent on manures, the salary of an agricultural chemist does not seem a very large item. And I feel sure that most estates, by learning how to obtain the best value for the money which they expend on manure, would more than save any contribution they might be called on to pay towards an agricultural expert's salary.

Those, on the other hand, who have rejected the proposal by reason of their disbelief in agricultural science, are, doubtless, veteran planters, who would point to the "good old times" and tell you that, without the aid of any new-fangled and scientific theories, they have got their bumper crops for many years by employing old and approved methods which have stood the test of time.

And, no doubt, an ounce of practice is in most cases to be preferred to a ton of theory. But I would ask, has the accumulated experience of these *laudatores temporis acti*,—some of it, perhaps, acquired in Ceylon,—proved itself capable of coping with the present state of things? With a rising exchange and falling prices, with the scourge of disease ever at our doors, are we in a position to despise any new methods, however speculative, however visionary? Are we in a position to condemn

without a trial, I will not say the magic of a Mr. Quarme, but even the "fairy tales of science"?

A Planter of no importance.

Kadur District,
9th March 1898.

TERRACING *vs.* DRAIN-CUTTING.

Sir,—I note with regret that "H. W. P." has felt constrained, through press of work, to conclude his share in what promised to be a very interesting correspondence. It is a great pity that those planters who have had actual experience in terracing their estates do not give the public the benefit of their knowledge. A contribution from Darjeeling would be especially valuable.

To refer to your correspondent's letter, which contains statements that appear very startling to me. He alleges that the Darjeeling terraces, of two or more feet in depth, have been maintained for years without any face walls and without *any slopes or loss of space for them.* In other words, that the sides of the terraces are perpendicular. This beats me altogether. For if terraces are made with perpendicular sides without retaining walls, it is very obvious that to obtain such sides one must cut into the solid below the terrace, throwing the loose earth on the terrace to be dug below. For it is utterly impossible to maintain *loose earth* in a perpendicular position for two or more feet in depth. Or is the "natural angle" of engineering a myth?

"H. W. P." says I assume impossible conditions in my argument about the loss of space from terracing *re* area occupied by the slope of the terrace wall. It may well be that the slopes of the terraces are always greater than the slope of the hill, but the mere fact of there being a slope at all proves my contention of loss of area occupied by that slope. To prove my point by an illustration familiar to all, *i.e.*, the excavations on bungalow sites or railway embankments. If a person stands on the edge of the embankment, he will find that there is a very considerable distance between him and the bottom of the excavated earth. The earth thus thrown down is not patted into any particular shape, it is resting at its own natural angle, and the looser the earth, the gentler will be the slope. It is precisely the same, on a smaller scale, with terraces. And the loss of area occupied by the excavated earth must be—given identical texture of soil—in direct ratio to the steepness of the hill side. The steeper the hill, the greater the necessity of terraces, with the inevitably greater loss in planting area. I can see no possible escape—on paper at least—from this dilemma.

I have no wish to write any further on the theoretical side of this question; indeed, I had hoped to have tested the matter practically ere this, but circumstances forbade. It will not be long, I hope, before I can set forth the results of my trials for what they are worth. For, wrong or right in my theories, I am determined to be right in practice!

A last word *re* loss of area, letting the slope question take care of itself. It is a common practice in hill districts to plant at a given number of feet apart, measuring the distance on the *surface.* Thus a steep hill side (1 in 2) planted at 6×6 (without reckoning loss of plants of rocks, drains, &c.) will give very nearly 1,400 plants against the 1,210 planted on the flat. I only mention this as a detail, for personally I am a great believer in wide planting.

"1 in 1."

GENERAL ARTICLES.

SUPPLIES.

How often in going around a coffee estate with a planter, he is heard to exclaim, "Do what I will, I *cannot* get my supplies to come on." I would in all humility give my views on this matter. First and foremost, then, good must be obtained. This is absolutely essential if you your supplies to eventually develop into sturdy hea bushes. Seed obtained from a district noted for its disease carries, I have observed, a taint of this disease i plants raised from such seed suffering more from *Hem Vastatrix* than plants raised from seed obtained from a trict where comparatively speaking leaf disease is norm less prevalent. Obtain these good seed, paying, if ne sary, a good price for it. You will find this truer econ in the end. Having obtained your seed, raise it in made for the purpose. Now the usual plan adopted for ting supplies out in the field is, if I am not mistaken, known and everywhere understood as "ball plantin That this is a most excellent mode I readily admit, bu the same time I maintain that "basket-planting" is a superior and more modern method; not, however, "bas planting" as is generally understood, not that pro where soil from a neighbouring shola is used to fill baskets, the seedlings being transplanted into these, k watered and allowed to grow until such time as the monso burst, when they are put out in the places assigned to th in the field. No, "basket-planting" is a splendid wa getting one's supplies to "come away," but I would haz the proposition that the basket should contain someth more than mere jungle soil. A mixture consisting in ev 5 parts of $\frac{2}{5}$ good jungle soil, $\frac{2}{5}$ths good cattle manu dried and reduced to powder, and $\frac{1}{5}$th sand is, I find, mirable. The seedlings, after having been transplan from the nursery beds to the baskets, very soon comme to grow, and by the time

> "The days are cold and dark and dreary
> And it rains and the rain is never weary,"

you have splendid plants in the full sense of the word. introduce, however, such a plant into an ordinary sheet coffee without having made preparations for its recept would be foolish. The plant has been brought up u the best of food, and on the best of food it must be ma tained. A month or so before actual supplying is taken hand, all supply pits should be re-opened and their conte scattered away from the pit. Then as soon as the S. W. m soon shows signs of "setting in" these pits should be filled with the surrounding *surface* soil. This soil on estate worked on modern principles, an estate that is wh is liberally manured, is usually rich in plant food; on this supply, having partially perhaps wholly exhausted the ginal nourishment contained in the basket, will thrive f year or two. After that it becomes a unit in a whole one many trees which go to form the entire estate, and is trea as such. The maiden crop from every "supply" shou be stripped early in the season, when in fact the bean is its embryo stage. This would enable the tree to establ itself thoroughly, would avert that catastrophe vulga known as "going back," so often experienced on you coffee under a heavy yield, and in the long run would p better. The third year of its existence would—certai should—find your plant vigorous, matured and prepar to carry, let us say, a 6 cwt. crop, and in every probabil this for a series of years. In thus writing I am not labo ing under a fit of *cacoethes scribendi*, but merely seeki for criticism, light that is, more light to lighten the da ness which even at the fag end of this XIX. century enwr many a thing, important and otherwise.

D.

CHEAP RAILWAYS FOR PLANTING DISTRICTS.

THE importance of good and cheap communications in
v districts or countries is undoubtedly great. Cheap and
cient communications are demanded by all. But very few,
eed, of the men whose voices swell the chorus take the
uble to possess a practical knowledge of the subject they
ofess to take such an interest in. The question of railway
mmunication is a strong case in point. "Give us, oh,
e us a railway!" is a cry frequently uttered by those
note from sea or rail highways. Now there are railways
d railways. There are broad-gauge, metre and narrow-
uge lines, the cost decreasing in proportion. A light
o-foot railway may not be perfection, but it is very cheap.
bridle-path is not exactly a "Queen's Highway," but
ves its purpose nevertheless. It resolves itself into a
estion of common business sense, and every intelligent
mber of the community should be able to take a part in
solution. The amount of traffic practically decides the
ality of the line. If very heavy, it would be absurd to
rtail initial cost on account of a temporary saving in
penditure. But if the traffic be light, as it usually is in
w or semi-opened districts, it would be still more absurd
burden the country with an expensive outfit in rails and
ling-stock that would have no chance for many years to
me of paying interest on its capital. Here, in South
dia, when a planting district urges the importance of
ilding a railway to tap its existing traffic and develop its
sources, the usual objection urged by Government is that
won't pay. This objection is invariably based on the
timated cost of a broad or metre gauge. With no grasp
any alternative gauge, the representatives of the district
ually have to subside for a while. After many years of
lay, the line is at last sanctioned, when the case, by mere
se of time, has proved beyond all doubt that the proposed
lway will pay well. But why this expenditure of time
d energy?

Government must be satisfied that a certain minimum
terest on construction will be earned. Roughly speaking,
ight two-foot six line will cost only half as much as a
oad gauge. Consequently, and bearing in mind the
proved carrying powers of the latest light lines, the
ances of a light railway proving a financial success are
st double those of its rival.

The present-day exponent of light railways is Mr. Calthrop,
no has proved, by the standing example of the Indian
arsi line, that light railways are eminently suited to
is country. In a paper read early last month before
e Royal Colonial Institute, Mr. Calthrop put the case
ry clearly. He supposed that a given colony had the
m of £600,000 to spend on railways. By spending £3,000
mile, it could get two hundred miles of line; at £6,000 it
n get one hundred miles; at £9,000 only a little over
ty-six miles. Now assuming that each mile produced
hundred tons of traffic in a year, the line costing
,000 a mile would bring forty thousand tons of traffic
port; that costing £6,000 a mile sixty-thousand tons,
d the cheapest—and longest—120,000 tons. To put
e case from another point of view—as the *Times of India*
ites—the burden of interest upon the earnings of each
ile. Supposing a guarantee of three per cent. is given
the Imperial Government, the quota that each ton has to contribute for interest is in the case of the shortest and most expensive line 9*s.* 9*d.* a ton; in the case of the £6,000 per mile line 6*s.* 6*d.*, and in the case of the £3,000 per mile line only 3*s.* 3*d.* But as a colony is in many cases a new country, needing development, it is of great importance to carry a line as far into the interior as it can be carried with profit. Here again the advantage of a light railway is demonstrated. As Mr. Calthrop puts it, "if it be possible to halve the estimated cost per mile of any projected line, you will get either twice the traffic area for the same money, or, if the line be restricted to the same length, the profits which it may earn will be, per cent. of capital cost, twice that of a line of double the cost, and consequently the prospects of a financial success are made much more certain." The colonies which take to light railway construction now will set out upon the enterprise under conditions more favouring than any that attended earlier undertakings of the same kind. The newer types of locomotive and rolling stock have revolutionized the whole process, and have secured the maximum return on a minimum outlay. Take one feature alone, the uniformity which Mr. Calthrop has introduced in the minimum axle-load. To borrow a definition of his, the maximum strength of permanent way upon any railway is controlled by the maximum axle-load proposed to be used upon it This axiom appears to have been lost sight of by earlier constructors of light railways, who in giving to locomotives a heavier axle-load than to wagons have had to provide an unnecessarily heavy rail. Mr. Calthrop has secured a maximum carrying capacity on the minimum weight of rail by adopting a uniform axle-load throughout the train for engines as well as wagons. But this is only one of the economies which come to the help of the latter-day constructor of light railways. The carrying capacity in relation to the weight of rolling stock has been increased to an extent that was scarcely dreamt of half a generation ago. The contrast between the new and the old *régimes* may be briefly indicated. The average English railway wagon weighs from four to six tons and carries a maximum load of seven or eight tons. The Barsi low-side wagon, which has now been in successful use in this country for a year, weighs 4 tons 2 cwt., and carries a maximum load of 15 tons 18 cwt., or nearly four times its own weight; the high side wagon weighs 5 tons 7 cwt. and carries 14 tons 13 cwt., and the covered wagon weighs 5 tons 18 cwt. and carries 14 tons 2 cwt.

SORTING TEA.

We believe that the tendency towards careless sorting is becoming universal, and that it should be checked, and perhaps the strongest reason in favour of more careful sorting is that the buyers and brokers complain of too many sorts. Take, for example, a merchant who dealt in coins: he would not object to finding several rupees in the bags of pice sold to him as copper only. It is strange that sorting machinery, instead of becoming more elaborate and delicate, has become more "simple," and the latest developments put temptations in the way of the Manager. A screw is provided at the lower end of the cylinder by which it can be depressed, *i.e.*, a ready road is opened to hurrying over the work when there is a press, and the tea can be *rushed* through. It is well worth thinking of. How much fine tea can you afford to present gratis to the buyers of your coarse tea, in order to save time and trouble? Is it just possible that you give away the price of an extra sorting machine by hurrying through one month's tea? Suppose that you make 72,000lbs. of tea in one month (= 900 maunds = 30 maunds daily), and that by hurried sorting you lose 3 per cent. of Orange Pekoe, and this Orange Pekoe loses 6 annas per pound by getting into the low grade teas. The sum works out 72,000lbs. × 3 per cent. = 2,160 × 6 annas = 12,960 annas = 810 rupees, which is the price of an extra sorting machine. We have purposely overstated the case, but do think that many estates throw away the price of a sorting machine during the course of one whole season, and that some few actually sacrifice Re. 1 per maund of tea by careless sorting. (The figures above show a loss of Rs. 800 on 900 maunds of tea.) The buyers like careless sorting because it saves them trouble and gives them better value for their money; the brokers like it because it saves trouble; the Managers like it because it saves trouble; and the inventors of machinery supply what is wanted. We can remember the birth of sorting machinery, and some of the earliest machines had oscillating frames, into which a hand sieve could be placed and removed when sufficient tea had fallen through. Later on we took to cylinders five feet in diameter with battens inside, and the tea received the treatment which turns cream into butter.

Now we find the cylinder to be about 3 feet in diameter, the different "meshes" are 3 feet long, so that the tea has hardly time to get fully sorted; then on a heavy day you can depress the cylinder and get the work done quicker. The machine referred to is admirably adapted for its purpose (which is not good sorting, but to suit the ideas of the Managers, brokers and buyers). With sufficient inducement the maker of the machine could turn out one which would give two Orange Pekoes, two Pekoes, Pekoe Souchong, Broken Tea and Dust. But the price of the machine would be greater. Or two of the above machines would sort well if not made to "do" a large quantity. Of course, the great inducement to hurried sorting is to have big "breaks," but a reference to the tea sales will show that small breaks of good teas sell well. Referring to the last tea sale, we find a Dooars garden sold 4 chests Broken Orange Pekoe at 10 annas and 23 chests Pekoe Fannings at 5 annas 8 pies. The Broken Orange Pekoe was 400lbs., the difference in price 4 annas 4 pies, and if that Broken Orange Pekoe had been put in or left in the Fannings, the loss would have been over Rs.100, because 400lbs. of good tea would not have raised the price of the 2,300lbs. of Pekoe Fannings. There is danger in over-sorting, because the tea can be made very grey if kept too long on the sieves, but the idea is not to get more Orange Pekoe by *longer* sifting: it is that the fine teas should be extracted *before cutting* and kept separate from the fine teas extracted *after* cutting up the bulk. We are writing from experience, and so can recommend others to try more careful sorting. On some estates the first operation is cutting up the tea in a Reid's breaker, which forces all the tea through a No. 4 sieve. This mixes up all the grades; pieces of Pekoe Souchong leaf will get int Orange Pekoe. On these estates it would be well to try how Orange Pekoe and Pekoe can be got out without any breakin these two teas should be kept separate. Having got out the " tea, the residue could be broken in the Reid's breaker and mad Pekoe, Pekoe Souchong and Broken Tea. This double sorting necessitate more machinery, but the difference in prices ob would pay for that and leave a profit. We believe so much in sorting that we think it would pay to buy tea in the marke re-sort it—extracting the higher grades from the lower and s them separately. A company formed for this purpose would a able to score by making big breaks for America. Supposing they bought 500 maunds of Pekoe and 500 of Pekoe Souchon re-sorting, they extract 5 per cent. Orange Pekoe out of the and 5 per cent. Pekoe out of the Pekoe Souchong, they would 25 of Orange Pekoe, 500 of Pekoe and 475 of Pekoe Souch *Indian Planters' Gazette.*

SAFFRON.

Saffron has lately been honoured with a newspaper noti Bengal. Since the wane of Muhammadan glory in India, the s has lost much of the estimation in which it was held by the ri a dye, a spice and a medicine. Its name is seldom heard now-a except when that luxury, *Polao*, is required to be made, consists of cooking rice with meat, in which preparation saff used as a spice and a dye, as substitute for turmeric. Inde have heard many people in South India call turmeric by the of saffron.

But saffron and turmeric are entirely different things, th being part of a flower and the other a root or rhizome. In t saffron is called *Crocos sativus* and turmeric is called *Curcuma* The vernacular names of saffron are:—Sanskrit, *Kumkum*; gali, *Jafran;* Hindi, *Kesar, zafran;* Tamil, *Kungumapu;* T *Kumkum apave.*

The newspaper notice the article has lately received connection with the preparations that are going on for the ma of the young Maharaja of Burdwan. It is said that a large qu of cloth has been dyed yellow with saffron for use on that f occasion. But saffron is too valuable a product for ordinary a dye, turmeric being employed instead. In Europe it is u colour cheese, pudding, &c. In India it is chiefly used as a med in fevers, melancholia and enlargement of the liver, and is als to possess stimulant and stomachic properties, being spe efficacious in catarrhal affections of children.

Kashmir is the only place in India where saffron is culti We heard many people say that Kashmir is the only place world capable of producing this substance. This is a mistake, is also largely grown in Persia, and this Persian product is small extent imported into India in the form of cakes. S worth more than five lakhs of rupees are annually importe India from foreign countries, mostly into Bombay, from F The article is also produced in China. The European demand is met by the product of France, Italy and Spain.

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

In the second year of his reign (1605 A.D.), on his way to Kabul, e Emperor one day halted on the side of the Behat river, which kes its rise from a fountain, called Virnag, in Kashmir. After ving a description of the fountain, the imperial author proceeds to eak of saffron :—"The river (Behat) expands much when it reaches ar the village of Pampur, which is ten *kos* from the city of ashmir. All the saffron of Kashmir is the product of this llage. Perhaps there is no other place in the world where ffron is so abundantly produced, the quality annually yielded ere being 5,000 maunds of Hindustan, or 4,000 maunds of Kabul Vilayet). I visited this place once with my father (Akbar) in e season in which the plant blossoms. In all other trees, we e they first get the branches, then the leaves, and after all the ower. But it is otherwise with this plant. It blossoms when it is ly about two inches high from the ground. Its flower is of a nish colour, having four leaves and four threads of an orange lour, in length equal to one joint of the finger. The fields of ffron are sometimes a *kos*, sometimes half a *kos* in length, and ey look very beautiful at a distance. In the season when it is llected, it has such a strong smell that people get headache from . Although I had taken a glass of wine, yet I was also affected y it. I asked the Kashmirians, who were employed in collecting it, hether it took any effect upon them, and was surprised by the eply, which was,—'they did not know even what the headache as.'"

On a subsequent occasion (1620 A.D.), Jahangir made a journey to Kashmir, passed through the tract of country where saffron is largely ultivated, and caused the following graphic account of the plant to e recorded in *Wakiyati-Jahangiri*:—"As the saffron was in blossom, His Majesty left the city to go to Pampur, which is the only place in Kashmir where it flourishes. Every parterre, every field, was, as far s the eye could reach, covered with flowers. The stem inclines wards the ground. The flower has five petals of a violet colour, nd three stigmas producing saffron are found within it, and that is he purest saffron. In an ordinary year, 4,000 maunds, or 3,200 Khurasani maunds, are produced. Half belongs to the Government, alf to the cultivators, and a seer sells for ten rupees; but the price ometimes varies a little. It is the established custom to weigh the owers and give them to the manufacturers, who take them home nd extract the saffron from them, and upon giving the extract, hich amounts to about one-fourth weight of the flower, to the public fficers, they receive in return an equal weight of salt, in lieu of oney-wages, for salt is not produced in Kashmir, and even in the eauty of the inhabitants there is but very little, *i.e.*, they have but ttle expression. They import salt from Hindustan."

Saffron was formerly a State monopoly in Kashmir, just as sandal ood is in Mysore at present. In Mysore, nobody is allowed to cut own a sandal tree, even if it happens to grow upon private land. This nasty pest is hard to get rid of; it will shoot forth and grow up s if under the influence of magic," remarked the owner of a garden disgust, as he uprooted a small sandal seedling with his hand, hile the writer some years ago was inspecting the fine fruit trees the an had reared in the neighbourhood of Seringapatam. Saffron is he dried flower stigma of the plant, not the entire flower. The igmas of nine flowers are required to make one grain of dried affron, or of 4,320 flowers to make one ounce of the marketable ubstance.—*The Wealth of India.*

DENITRIFICATION OF MANURE—THE OTHER SIDE.

II.

We shall now attempt to summarize the results of such f the world-famous Rothamsted experiments as bear on he interesting question under discussion. The German nvestigations may be considered to have proved that the conomic use of artificial fertilisers is impossible with xcessive quantities of stable manure of a certain condition. The results will now be considered of using nitrates and ther nitrogenous manure with the *usual quantity* of stable manure adopted in field practice.

In the field devoted to the culture of roots at Rothamsted, ays Professor Warrington, a considerable portion of the land has received annually for many years 14 tons of farmyard manure per acre. One half of this land has received in addition 3½ cwt. of superphosphate each year. These two farmyard manure plots are each divided into five portions, one receiving no further manure, the others cross-dressed respectively with nitrate of sodium, sulphate of ammonium, rape cake, and sulphate of ammonium with rape cake. Each cross-dressing supplies a known quality of nitrogen. What has been the effect of these cross-dressings?

Wagner mentions, at the commencement of his paper, that, under the conditions of practical agriculture, 55 per cent. of the nitrogen of nitrate of sodium may be expected to be recovered in the crop. In the pot experiments we have earlier mentioned the return has varied from 55 to 77 per cent. In the Rothamsted field experiments with barley, nearly 60 per cent. of the nitrogen of a moderate dressing of nitrate of sodium has been on an average recovered in the increased produce where a liberal amount of ash constituents has been supplied. Sulphate of ammonium Wagner finds to give on an average one-tenth less return than nitrate of sodium for the same amount of nitrogen applied. Bearing these facts in mind, the percentage of nitrogen recovered in the increase of crop by the use of nitrate of sodium and sulphate of ammonium in the mangel experiments appears quite satisfactory. The nitrate of sodium employed as a cross-dressing is utilised to the extent of 53·6 per cent. where 14 tons of farmyard manure are applied, and the utilisation reaches 68·9 per cent. where superphosphate is also employed. With ammonium salts, the utilisation under these two conditions is respectively 58·0 and 67·3 per cent. It will be observed that although superphosphate and farmyard manure give no greater crop of roots than farmyard manure alone, yet, when nitrate or ammonia is used in addition, the presence of the superphosphate produces a considerably greater increase of crop. The supply of phosphates becomes insufficient only when the supply of nitrogen is increased. We shall see presently that still better results were obtained when potash was supplied as well as phosphates. The cross-dressing of rape-cake has been utilised to the extent of 47·3 and 50·7 per cent., without, and with superphosphate. As the rape-cake itself supplies both phosphates and potash, the effect of additional superphosphate is here little perceived. The very heavy cross-dressing of ammonium salts and rape-cake, supplying 184 lb. of nitrogen per acre, is utilised to the extent of 48·6 and 50·7 per cent. under the conditions already mentioned.

It will be seen that when nitrate of sodium, or ammonium salts, were applied to land manured with superphosphate and sulphate of potassium, the increase in the quantity of nitrogen in the roots by the addition of these manures was practically the same as was obtained when these cross- dressings were applied to land receiving farmyard manure; the 14 tons of farmyard manure had thus no depressing effect on the action of the nitrate or ammonia. That the leaves, if taken into account, would not alter this conclusion is shown by the fact that the proportion of leaf is greatest in every case on the farmyard manure plot; the proportion of nitrogen recovered in the crop would thus be more increased on this plot than on the other, if the nitrogen in the leaf was taken into account. Where rape-cake is used with the farmyard manure we do not get so good a return in the roots as where the rape-cake is used without dung; with 2,000 lb. of rape-cake and 14 tons of farmyard manure we apparently reach an amount of organic manure in excess of what can be economically employed in an average season.

Notwithstanding the excellent utilisation of the nitrogen of the nitrate of sodium or ammonium salts when applied with dung to mangels, the increased weight of crop obtained from these cross-dressings is by no means so great as when the same cross-dressings are applied without farmyard manure. Thus the increase in root and leaf yielded by the nitrate of sodium on the farmyard manure and superphosphate plot was 9 tons 9 cwt., and that yielded by the ammonium salts 8 tons; while, without farmyard manure, the increase from similar dressings applied to land receiving superphosphate and sulphate of potassium was respectively 14 tons 5 cwt. and 11 tons 19 cwt. This considerable difference is due to the fact that nitrate of sodium or ammonium salts give a smaller, but *much more nitrogenous* increase when applied to dunged land than when applied to land receiving no other nitrogenous manure. The fact is of considerable practical importance to the farmer, but it has nothing to do with the question before us, which is: Does farmyard manure

interfere with the assimilation of nitrogen from other manures? That a smaller return is obtained in crop, per unit of nitrogen, as the supply of nitrogenous manure is increased is a fact sufficiently familiar to the agriculturist.

It is now, I think, clear that under the conditions in which farmyard manure is employed in the mangel field at Rothamsted the addition of a dressing of nitrate of sodium is attended with a good return for the additional nitrogen applied: this fact is shown by the earlier results when the nitrate was applied before the dung; it is shown still more in the later experiments, when the nitrate was applied as a topdressing to the young plants, and when the supply of potash to the crop was at the same time increased. The amount of farmyard manure employed in the Rothamsted field is a moderate quantity, and we must not therefore conclude that no deterioration in the action of nitrate of sodium will take place where much larger quantities of dung are made use of. The danger of denitrification reaching considerable proportions will increase as the amount of fermentable organic matter in the soil increases, and will be much aggravated by a wet condition of the land. The horticulturist employs dung in large quantities is much more likely to suffer denitrification than the farmer.

The mode in which farmyard manure is applied and the exte which it is incorporated with the soil must have some infl upon its action. When farmyard manure is ploughed in, it i intimately mixed with the whole soil, as in a pot experiment, left in a succession of layers separated by unmanured soil. roots are grown on the ridge system, the farmyard manure is fined to the centre of the ridge. In either case the denitrifying z limited in extent, and does not include the whole of the soil penet by the roots. There is clearly much scope for careful inquiry the most profitable method of employing dung with other ma

The results furnished by the field experiments at Rothamsted farmyard manure do not thus substantiate the conclusions o German experimenters; the results obtained by the latter wer to the special conditions of their experiments, and especially t large quantities of dung or straw they employed.

Apart from the subject of denitrification, there are many fa great practical value which are taught by the German experi which we had under consideration. Persons unfamiliar with method of pot experiments are apt to disregard the results obt in this way. It is foolish to do so. Pot culture, with the opport it gives of maintaining exact experimental conditions, is, indee only trustworthy method for the solution of many questions.

One fact which comes into great prominence in the Germa periments is that ordinary farmyard manure is valueless as foo plants until it is nitrified; this is surely the only conclusion w draw from the want of action of the manure when applied in quantities in the pot experiments. In the light of these result economy of large dressings of farmyard manure becomes questionable.

The conditions most suitable for the nitrification of conside masses of organic matter deserve attention. Dehérain's few periments on the subject are very suggestive. He mixed 100 of ordinary dry soil with 5, 10, 15, 20, and 25 parts of water; p these mixtures in a saturated atmosphere, so as to preserve uncha the proportion of water added; and at the end of ninety determined the quantity of nitric acid produced. A simila periment was made with soil with which 2 per cent. of farm manure had been mixed. The results found were as under:—

Water added to 100 soil.	Nitric acid formed per million of soil.	
	Natural soil.	Soil with farmyard ma
5	250	270
10	260	360
15	270	490
20	290	290
25	380	220

We see, then, that while nitrification proceeded more energeti in the natural soil with each increase in the amount of water a up to 25 per 100, this was not the case when farmyard ma equivalent to 20 tons per acre, was present. In the case o manured soil, much the best result was obtained with 15 of per 100 of soil. With 20 of water per 100 of soil there wa benefit from the addition of the manure; and when the water rea 25 per cent. the soil contained much less nitric acid than if no f yard manure had been applied; denitrification had clearly active in this case. Dehérain's results were not free from irregu ties, and deserve careful repetition; they are, however, quite sistent with the general ideas as to the most suitable condition the nitrification of organic matter furnished by the prolonge perience gained in France as to the most profitable way of mana artificial nitre beds, which in that country were kept under c These beds consisted of heaps of organic matter undergoing nitr tion. The proportion of water present was found to be of importance. As nitrification advanced this proportion was care diminished. If this precaution was neglected very little nitre finally obtained. We should judge, therefore, that moderately soils are those most likely to yield a profitable return with farm manure.

THE MADRAS SALES AND AGENCY COMPANY, (LD.)

Capital Rupees 24,000, with power to increase. Registered Office, Nos. 17 and 18, Popham's Broadway, Madras.

ıe immense difference between the manurial value of the solid liquid excrements of animals is shown in a striking manner in German experiments; and the analysis of the dung, and of the ıyard manure which they employed, showed that their effect on ɔs was plainly connected with the proportion of soluble and ve nitrogenous matter which they contained. The original void- of the animal have a far greater manurial value than the final luct of the manure heap which the farmer carries to his fields. he whole progress from the stable to the field the loss of nitrogen oing on, this loss falling on the most valuable constituent of the ıure, and resulting finally in a residue of comparatively inert ter. Maercker estimates the loss of nitrogen in the ordinary paration of farmyard manure as equal to 45 lb. per beast in one r. One practical conclusion from these statements is the economy eeding animals *on the land* whenever practicable. The whole ject of the economic preparation and preservation of farmyard ıure is being actively investigated in Germany.

DISTRICT ASSOCIATIONS.

NELLIAMPATHY.

Proceedings of a meeting held at Victoria Bungalow, Monday, h February 1898. Present:—Messrs. Everington, Fenton, E. nes, F. Jones, C. Hall, Watts and J. C. Abbott, *Hony. Secretary.* . E. Jones in the chair.

Proceedings of last meeting were taken as read.

Hospital.—Read letter from the Dewan forwarding copy of his oceedings showing that the establishment of a hospital on the lliampathies had been sanctioned on the terms agreed to by the sociation. Recorded with satisfaction.

Quit-rents.—Read letter from the Dewan and copy of his Pro- dings, in which various objections were made to the present tem of paying quit-rents by cheque and asking the opinion of the sociation. Resolved "that this Association admits that there are ections to the present system, and is prepared to accept the sugges- n of the Dewan that payments should for the future be made in h or currency notes."

Agricultural Chemist.—Read letter from the Secretary, U. P. A. I., stating that the scheme for securing the services of an Agri- tural Chemist had met with so little support that it would have be abandoned.

Roads.—The Hon. Secretary was requested to write to the Chief gineer with reference to the bridge at Poothoonda, the approaches which are usually flooded during the monsoon. It was agreed at Mr. Dupen be asked to construct the foot bridge at the bottom the old ghaut. A vote of thanks to the Chairman terminated e proceedings.

E. JONES, *Chairman.*
J. C. ABBOTT, *Honorary Secretary.*

WHAT MAKES THEM CRY?

You have a very sore finger, let us say. It may be a hurt, a boil— worse still, that fearfully painful thing, a felon. Oh, my! oh, my! hat a time you have been trying to protect that poor finger. It all the time getting hit or knocking against something. Simply keep it out of harm's way worries you more than doing a day's ork; and you don't succeed—and wouldn't even with a dozen licemen to help you. You are scared of a fly threatening to light it.

That is the principle on which Mrs. Elizabeth Allen couldn't bear e least noise. She had no sore finger, but she had what was still ore sensitive—a body full of sore nerves; weak, starved, unstrung rves. So the prattle of children, the closing of a door, the momen- ry roar of a wagon in the street, the clatter of dishes in the kitchen, e thousand and one sounds and noises that are in the air constantly why, the smallest of them struck her like a blow from a club. oises which are not regarded by a well person are like volleys of usketry to one in this condition. Millions of women know all about and plenty of men too—crowds of them. You recognise them on ght—those who are subject to this affliction. Their lined foreheads, eir bright, suspicious eyes, their self-protecting gestures and anner—you've seen them. Perhaps you are one of them yourself. If so, you'd give all your money and mortgage your future to have stronger set of nerves, wouldn't you? Let's talk about it two minutes, first quoting the lady's letter, which is dated May 11th, 1893, and written from her home, 263, Syston Street, Leicester.

"For many years," she says, "I suffered from indigestion and weakness. After meals I had a great pain at my chest. Every few days I had an attack of sick headache, and had to be constantly lying down on the couch; I strained and heaved a good deal, and spat up a sour nauseous fluid. As time went on I got very weak and nervous, and couldn't bear the least noise.

"I took all sorts of medicines and consulted doctors, but nothing did me much good. Later on I came to hear of Mother Seigel's Curative Syrup, and after taking it a short time the disease left me, and I was able to relish and digest my food. Owing to the virtue of this remedy I now keep in good health. (Signed) Elizabeth Allen."

And here is Mr. W. Nash, who says: "For fully ten years I suffered from periodic attacks of biliousness. At times a severe headache, preceded by excessive drowsiness; at other times vomiting, and retching for a whole day; at other times sleeplessness, pain in the chest, side, and stomach, coated tongue and bad breath—that was the way it acted with me. I grew very melancholy, and was not able to follow my business. I consulted doctors and used tonics, &c., but they only made me worse.

"I had constantly heard of your wonderful remedy, Mother Seigel's Syrup, but didn't believe in it. Then I read in *Wit and Wisdom* of a case like mine that the Syrup had cured; so I tried it, and the first bottle acted like magic. The pains left me the first week; I repeated my food no more, *and in a month all my ills were gone. Bless Mother Seigel for ever,* I say.—Yours gratefully, (Signed) W. Nash, 331, Goswell Road, E. C., London, October 2nd, 1893."

Now, where is there room enough on paper to sufficiently praise a medicine that will do what this one did for these two good friends of ours? All pain, remember, is nervous pain, and in the above case it was the foul and inflamed stomach which, by stopping digestion, starved the nerves and made them cry out. What won't cry out when it is starved? Babies will, men will, women will, nerves will.

Mother Seigel's medicine set the stomach in order and gave the nerves some food. Then what? Why, quiet, comfort, strength, rest, enjoyment. "Bless Mother Seigel," indeed.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (February 25, 1898) says:—A good demand prevailed at auctions this week for all desirable descriptions, and the moderate supplies were nearly all disposed of in seller's favour.

Over 3,000 bags East India were offered and attracted good competition, fine colory grades realising extreme rates and medium qualities fully previous values.

Only small quantities of Central American kinds were catalogued, and these sold at steady prices, except the commoner sorts, which went in buyer's favour.

Futures have been quiet, and there is little change to note in quotations, fluctuations having been unimportant. The market closes 3d. to 6d. lower on the week.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending February 23rd, 1898, says:—Bank rate 3%. Bombay Exchange closes at 1s. $3\frac{3}{32}$d. Brazil Exchange $6\frac{11}{16}$d. Rupee paper $3\frac{1}{2}$% $63\frac{5}{8}$. Silver $25\frac{5}{8}$d. per oz.

All good qualities continue to be well competed for, other kinds being quiet and about steady. The demand for East India has been very good, and we quote an advance of 1s. to 2s. per cwt. on medium, and fully 2s. on fine which is scarce. Brazil markets are firmer.

Daily receipts averaged 10,300 bags in Rio, and 10,100 bags in Santos.

Futures close quiet, about 3d. to 6d. lower, viz.:—Good average Santos in Havre, March delivery, fcs. 37.25, in Hamburg pf. 30, and No. 7 low ordinary Rio in New York $5.60.

To-day's London official quotations are:—

	Feb.	March	May	July	Sept.	Dec., '98.
Santos ...	29/6	29/9	30/6	30/9	31/3	31/9

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 3, Esplanade Row, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 1st April, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Coorg.

POLLI BETTA, 23*rd March.*—*Weather.*—During the past two days it has clouded up, and rain has fallen somewhere, as the thunder could be heard, probably where it is not needed. Anyhow it is confident that we shall be getting it soon. *Crops.*—Spike still holding out, but rain required soon to set large crops. *General Health.*—Influenza about as bad as it can be.

Nellampatty (British).

23*rd March.*—*Weather.*—Strong east wind ceased last week, since when we have had sea breeze, and clouds are now banking up and rain is not far off. If it comes soon, it will suit everyone, as spike that did not come out last rain is very forward and won't stand much longer. Blossom seems to have set fairly well and only wants rain to swell it now. *General Health.*—Fever showing up strongly among us.

Lower Pulneys.

DINDIGUL, 23*rd March.*—*Weather.*—No rain since 14th February, and no signs of any so far. Estates on the southern slopes, where a first blossom was out on 22nd and 23rd February, are more in need

of immediate rain than other parts of the district. *Crops.*—1897-98 shortest on record. Very fair spike all over the district, and if we get rain by first week in April, large crops will be picked. *Plant-diseases.*—No signs of leaf-disease now. Green bug commencing to show itself in parts. *General Health.*—Fever prevalent, as it usually is at this season of the year on the Lower Pulneys and Siroomullay hills. *Labour.*—Plentiful.

Nellakota. 16*th March.*—*Weather.*—Cloudy two days last week, and looked like rain. Sky clear now—blazing hot—and strong E. wind blowing. *Crops.*—The small blossom that opened in January has set very well Fine show of spike for coming crop, but rain needed badly. Rice 8 measures, grain 11 measures, ragi 16 measures per rupee in local bazaar. Why do prices of grain imported from Mysore still hold up? *Plant-diseases.*—What little leaf disease there was has all passed off. Trees this year have been left with sufficient foliage to give them a chance of wintering, and they are taking full advantage of the opportunity. *General Health.*—Colds and fever everywhere—due to the E. wind. It may be seasonable, but it is very unpleasant. *Labour.*—Paid off; local labour ample for what little work remains. *Interesting Items.*—The past has been the best season for snipe we have had for many years. Fires more numerous than I have ever seen them. The whole country lies under a pale of smoke: and this, with the heat and dry wind, makes existence the reverse of pleasant. Advance Jupiter Pluvius, and again I say advance.

Nilgiris. COONOOR, 22*nd March.*—*Weather.*—The cold spell we have been having lately has turned to very warm weather, the high winds dropping. Up to a week ago frost has occurred in cold localities near Coonoor,—most unusual for this time of year. *Crops.*—The coffee blossom out on the lower estates was a very good one, but unless rain falls soon a good deal will be lost. On higher estates only a quarter blossom or less has come out to date. The change in the weather is putting some heart into tea, though our March flushes are behind the average made up partly by February. *Labour.*—Labour is abundant and lots of maistries seem on the move. *Interesting Items.*—Progress on the Railway; small amount of work still to be done does not augur well for its alleged June opening. It is possible that the next century will see it running. *General Remarks.*—Measles rather rife among coolies, and health generally indifferent.

KULLAKAMBY, 24*th March.*—*Weather.*—Fierce sun and strong east wind continue, though at night there is a suggestion of rain in the air. Rainfall since January is, so far, only one and-a-half inches, though neighbouring estates have had over four inches. *Crops.*—Spike still good and healthy looking, and on most estates will hold out till the end of the month, when rain may be expected. *General Health.*—Good. *Interesting Items.*—The 23rd was the Telugu New Year's day, and most estates gave all hands a holiday—a fact which was loudly proclaimed by tom-toming and other hideous noises essential to the coolie when keeping a feast. Numerous scrub fires have occurred, and two estates had narrow escapes from damage to coffee trees.

WHY THE SOIL IS CULTIVATED.

As we explained in our last issue, the chief reasons for cultivating the soil are to control the conditions regulating its moisture, and to enable plant roots to freely extend t growth in all suitable directions. In continuing our di of Mr. Milton Whitney's article—Mr. Whitney is in the U Department of Agriculture, and his special branch is A cultural Soils—we have now to deal with the principle plowing. The practice of using plows for stirring and inv ing the top layers of the soil is as ancient as it is cheap. no means, however, can it be considered perfect. Trenchi and digging, if properly done, are immeasurably superior the thorough way they loose and aerate the soil. Continu ploughing at the same depth results in a "plow-pan," *i.e.*, soil gets compacted at a certain distance from the surf by the dragging action of the share. Hand-digging is f from this defect, as the soil is broken off and not slid What is known as "mamoty scraping," however, undou edly forms a pan, though only a surface one. Rain being able to penetrate the hard, smooth surface, rush violently off the soil and carries away with it the thin layer loose soil lying above the pan. Mr. Whitney, in alludi to the subject of wash, states that lightly plowed la washes very badly. Soil kept undisturbed washes ve little, while deeply-plowed soil will hardly wash at all. T reason is so simple that we cannot but wonder that plante do not generally accept it. The deeper a soil is cultivate the greater the proportion of water it can hold within pores.

Of the practical value of sub-soiling, little is definite known. As a general principle it may be laid down th sub-soiling is rarely necessary in light porous soil, or districts where light showers are frequent. It is n beneficial in heavy wet soils, unless they are previous thoroughly under-drained. If the subsoil is acid, it will a as a poison if brought to the surface in any quantity. C plantations, deep subsoil cultivation can be carried o easily enough without running the risk of any such dange Renovation pits, if dug at all, should be dug very shallo especially if the subsoil is poor and acid (the litmus pap test can be used to test this latter point). The bottom the pit should be then deeply forked. Continuous trenches they should also be shallow—would be still better; forki the bottom of the trenches is of course necessary. Needle to say, unless a thorough "wintering" is needed, su operations should be performed in the monsoon and the p or trenches partially filled in during the hot weather. in all deep cultivation, these operations eventually result the soil being able to retain a far greater percentage moisture, though its immediate effects are dessicatory.

Surface cultivation, on the other hand, should be performe either in dry, or during light showery, weather. T object is to form a mulch to stop the evaporation of wat drawn from the subsoil stores. During active growt

ep cultivation is a great mistake, as it injures the feeding tlets. It will be of interest to coffee-planters to learn t light cultivation, if continued too long, will injure the p by retaining too much moisture within the soil, delaying the ripening. This of course refers to grain crops. With it, the injurious effects of a long drought in early cropne are well known.

Under-drainage, while drawing off excessive moisture om the soil, allows the soil to retain the maximum of oisture conducible with health to the plant. Water, as ch, does no harm to most plants even if their roots are mersed in it. But it is essential that such water must be pt perfectly aerated. Centuries ago, the Romans used plant their irrigated crops on very high ridges, so as to low them all the moisture they could possibly need, while moving all danger of the soil or water becoming sour round ne plant roots.

Coffee irrigationists should keep this danger well in mind. ile drainage is, of course, the most effectual of all styles of rainage, but its cost is great. Stiff clay soils are naturally ost benefited by under-drainage.

From under-drainage we naturally turn to irrigation. It a great mistake to suppose that the artificial application f water to crops should be confined to arid regions, which, vithout such extraneous aid, would remain absolutely barren. rrigation is successfully adopted in countries whose rainall, though ample in its total quantity, is irregular and not o be depended on.

"The object of all cultivation, in its broadest aspect, is o maintain, under existing climatic conditions, uniform and dequate supplies of water and air in soils, adapted to ifferent classes of plants. This is the object alike of lowing, subsoiling, cultivation, under-drainage and irrigaion; they are all processes to be used in maintaining suitable oisture conditions for the growth of crops."

NOTES.

Liberian in South Travancore.

From one thing or another, the great hopes once entertained of Liberian coffee in South Travancore lo not seem to have been well grounded. We hear from a correspondent that most young clearings of this variety are being abandoned.

Wara fibre.

Planters having poor land near the sea level might do worse than put it down to Wara fibre (*Calatropis gigantea*), writes the *Produce World*. Samples of this fibre placed on the London market have been ranked with the finest rhea and valued at £36 to £38 per ton. It does well on poor and low soil.

The Kaiser as Coffee Planter.

According to the *Figaro*, says the *H. & C. Mail*, the German Emperor has recently acquired a coffee plantation in a German settlement in East Africa. With him are three associates; it is to be worked jointly as a commercial enterprise, and the Kaiser has full confidence in the success of the scheme.

How the Rupee affects Ceylon.

The prospects of a continued high exchange are having their inevitable results in Ceylon. Accordingly the question of abandoning tea yielding under 300—350 lbs. per acre is under serious discussion. It is computed that a loss of ten million rupees was inflicted on the Island tea industry last year by the rise in exchange. A 1*s.* 4*d.* rupee for the whole of 1898 will all but ruin the whole producing industry of India and Ceylon.

"A rose by any other name."

It is always gratifying to us to find that the public benefited by the pabulum provided in these columns is by no means confined to the readers of our journal. So highly, indeed, do certain of our contemporaries appreciate our efforts, that they have fallen, unconsciously of course, into the habit of presenting *verbatim* extracts from our pages to their readers as their own. Can flattery go further? And yet we are misguided enough to imagine that the simple affix of our name to those choice extracts would render to them a savour they do lack at present, to our nostrils at least.

The Kangra green tea trade.

The green tea trade of the Kangra Valley has fallen on evil days, and efforts are now being made to resuscitate the industry. Local prices for green tea are as low as 7 as. per *hatti* of 4 lbs., while in Central Asia the same article is retailed at Rs. 7 the *hatti*. The great need is of course a good and safe trade route to tap the Central Asian markets. Local planters have commenced their plan of campaign, the first steps of which are to do all they can to urge upon Government to direct their officials to protect and push in British trade in the regions under notice. One of the features of the movement is the hearty co-operation between European and Native planters.

Tea in 1898.

The *Indian Planters' Gazette* views the prospect for the current year with none too sanguine a view. Last season's outturn was considerably under the first estimate, but with the 18 to 20 thousand acres coming into partial bearing, prospects are not bright. It is possible, nay probable, we think ourselves, that picking will tend to become finer than ever, which will help substantially to keep the yield from becoming altogether too large. To secure the new markets, of which everyone is talking, our contemporary shrewdly remarks that the present capital allowed for the purpose is far too small. And in fact, it adds with exaggerated feeling, if the money cannot be raised in London, all idea of pushing the trade should be abandoned.

Croton tiglium.

The seeds of the *Croton tiglium*, says the *Produce World*, a plant which grows wild all over Lower and Eastern Bengal, are now in large request and are sold at £1 per 1,000, and larger quantities at reduced rates. The present demand for them,

however, appears to be a trade secret so far, says our contemporary, but we believe that the seeds are used almost exclusively for the preparation of the extremely powerful purgative, croton oil to wit. The plant will grow and thrive on any soil, no matter what the quality of it, and there is no reason why its cultivation should not be introduced on abandoned portions of plantations. The seeds are known to be of a very unctuous nature, and there would consequently be considerable loss in weight in transit to foreign markets due to fermentation. The tree will grow from the sea level to an elevation of 3,000 feet and even over. Once a week a cooly shakes the tree and picks up from the ground what has fallen off, puts the pods in the sun, shells them, and gives another drying, which is all that is required. A net profit of about one shilling per tree per annum has been realized from full-grown trees.

Indian Teas. There is a steady demand, and as the supply continues moderate, prices show no material change for the lower grades, while an upward tendency is marked in the better descriptions. For the latter there was active bidding at firm to advanced rates, and in some cases a rise of ½*d.* to 1*d.* was established in the finest qualities. There is every prospect of a very firm market for fine teas giving a strong infusion, as the quantity on offer is getting into a limited compass, and judging from recent reports there is not likely to be any important addition to the stock. All useful medium kinds met with a fairly active inquiry, and are more difficult to obtain at prices ruling two or three weeks ago, the stronger position being no doubt due to the disposition of buyers to secure a good working stock at present prices. It appears almost certain that there will not be more of this class of tea than the trade can conveniently absorb, and for this reason it is expected that the market will be stronger later on. Although no appreciable change in the values of the lower sorts has taken place, prices have been somewhat irregular, and in some cases in buyer's favour. The public sales comprised 32,923 packages and 3,191 were withdrawn.

Mexico. The *Ceylon Observer* writes thus :—

"One result of the establishment of an artificial, dishonest rupee in India and Ceylon has, undoubtedly, been to send capitalists hitherto interested in the East, to seek investments in 'silver' countries of the Far West. Messrs. H. K. Rutherford, G. A. Talbot, and other gentlemen well known in Ceylon have given attention to Brazil and invested freely in extensive coffee property there. Mr. Huntly Thring, Mr. J. L. Shand, Mr. R. P. Macfarlane and others have made an investment in Costa Rica; and now an influential Syndicate of Ceylon men have—according to our London correspondent—completed the purchase of coffee property in Mexico. It is well that these facts, and many more similar to them, should be brought under the notice of Mr. Chamberlain and Lord George Hamilton to give them some idea of what India and Ceylon have lost, and are losing, through the transfer of capital and planting enterprise to America, which would surely have been given to the East had the currency not been tampered with."

Of all American lands Mexico seems to offer the brightest prospects to investors,—a firm and just administration, unparalleled in the South American Republics, great and extending railway lines, excellent climate, vast areas of splendid land *and a silver currency*. In 1895 the population was 13 millions, 19 per cent. being pure white, 43 per cent. mixed, and 58 per cent. of Indian race. The exports of co and cacao are steadily increasing; in 1894-95 coffee expo surpassed 300,000 cwt. Almost every conceivable tropi and sub-tropical product grows luxuriantly, while the pr imity of American and European markets gives the produ an immense advantage over his more remote rivals.

Coffee in Queensland. Despite the occasional reports the spread of coffee cultivation Queensland, the progress there is excessively slow. Far ers hold that it will be impossible to compete with the che labour countries, though if Brazil is considered, with its a-day Spanish and Italian labour, such fears may be held be groundless. Providing of course that, soil and clima being favourable, nothing is attempted in the way of toppi and its resultant increase in work. We would advise c Queensland readers to attempt nothing more, for the prese at least, than growing coffee *au naturél*, which, bei interpreted for their benefit, means planting out, after thorough plowing, the young plants at about 12 feet apa each way. This will allow space for horse cultivators to run between the rows, and will obviate expensive han weeding and digging. The plantation should be thorough protected from high winds. The kind of shade suitable the locality must be ascertained from experience. If t first or maiden blossom is heavy, the labour expended stripping it off, and thus sacrificing the first crop for t future benefit of the tree, will be found well worth t expenditure. No topping should be attempted, and t trees must be allowed to grow to their natural height so 15 feet or less. The beans will of course tend to be inferi to those from topped and pruned coffee, but in the loc retail market the differences will not be found very extren The cost of picking will be the only serious expense, a will vary in inverse ratio to the crop on the trees.

The London Market. The market has again settled dov into a very quiet state, writes t *Produce Markets Review* of the 26th ult., the continu heavy receipts in Brazil having acted adversely in t terminal market, where prices have drooped, though on to the extent of 6*d.* to 9*d.* per cwt. At auction there h again been a good demand for all fine qualities. Ea India has sold at a slight advance for the few good parc

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain p ton :—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed fr the parent trees of above analysis at Rs.6 per pound containi about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere sa from the

MANAGER, ARIENKOW ESTATE,

Shencottah

ered, but the medium and common kinds are rather ver. The few lots of Plantation Ceylon have sold well relatively high rates. Larger arrivals of Costa Rica are orted, but much of the coffee having been shipped in parchment has to be cleaned, and will not be ready til next week. The few lots offered have sold well, ough hardly at the very extreme prices obtainable cently. Of other kinds, Colombian has sold irregularly, ile Jamaica, mostly of very common quality, has sold a decline.

offee prospects in Hawaii.

With the prospect of the 1*s.* 4*d.* rupee becoming a permanency, it is as well for capitalists to turn their ttention to other countries for the scene of their labours. Hawaii has of late attracted considerable attention as a coffee country, and the British Consular's estimates of the cost of cultivation, &c., will be found interesting. They include the purchase of 100 acres of Government land at 10 dollars (say £2) per acre :—

	Dollars.
Outlay, 1st year	6,955
„ 2nd year	3,080
„ 3rd year	5,070
	15,105
By 20,000lb. (below 2 cwt. per acre) of coffee at 18 cwt.	3,600
	11,505
Outlay, 4th year	6,220
	17,725
By 60,000 lb. coffee	10,800
	6,925
Outlay, 5th year	7,570
	14,495
By 85,000 lb. coffee	15,800
Credit at the end of 5 years ...	805

We then get an outlay in the sixth year of 8,820 dollars and a credit of 100,000 lb. of coffee equal to 18,000 dollars, and in the seventh year the crop is 125,000 lb. against the following outlay :—

	Dollars.
Manager's salary	1,200
Labour, 12 Japanese	2,160
Picking, pulping, and drying 125,000 lb. of coffee, at 4 c.	5,000
Hulling, polishing, and grading 125,000 lb., at 1 c. ...	1,250
Sundries, bags, freight, etc.	1,200
	10,810

The result after seven years is a balance to credit of 21,675 dollars (not counting interest), and of course a valuable property

To break up hailstones.

In alluding to the great damage done by hailstones to crops generally, the *P.L.G.* turns the attention of its readers to the use of aerial explosions of dynamite to break up the hail formation and convert it to beneficial rain. Experiments to cause rain, from apparently cloudless skies, have not altogether proved successful, but the effects produced have led scientists to devote attention to the disruption of passing clouds; not only have these bodies of vapour been arrested, but the moisture they contained has been precipitated on the earth immediately below the point of disruption, and from this the operators adduce the possibility of splitting up a hail cloud ere its particles assume the character of ice, thus depriving it of its destructive properties, either by causing its precipitation in the shape of simple rain, or, at the most, so reducing the size of the "stones" as to render them next to harmless. The experiments were carried out near Malaga, in Southern Spain, by means of parcels of dynamite attached to small balloons, sent up as the storm clouds gathered, the wire which held the balloon captive being connected with the explosive and also with a battery on *terra firma;* the result was that over a space of several square miles, to which the effects of the explosion extended, the vines received merely a drenching shower, others, lying beyond range, suffering in the usual manner from the hail. The cost of the apparatus—wire, balloon, battery and explosive, if compared with the value of the flush that would be saved—would be small enough; but as every planter knows, it is not so much the loss of a single flush but the after-effects of a "cutting up" that throws a garden's outturn back. The method of manipulation of the battery, etc., could, we presume, be soon learnt, and surely the diminished yield that hail causes, for sometimes a couple of months, or, we may say, for the whole season, should induce planters to study this important matter. Day by day science brings forward some means of counteracting the destructive power of natural phenomena, and it behoves all interested to avail themselves of these.

The opening up of China and the Tea Trade.

China is to be opened up to the trade of the world. Its splendid waterways are to be free to British and other steamers next June, and the collection of the "likin," or internal customs, will, it is said, in connection with the new loan, says the *Home and Colonial Mail,* come under the control of the Inspector-General of Maritime Customs, who, so long as British trade with China at the ports continues to exceed that of any other Power, will be a British subject. Every effort will, therefore, be made to develop the trade of China, especially that of tea. In 1896 the gross amount of Chinese trade was 343 millions of Haikwan taels, about six of which go to the pound sterling. In round figures Great Britain, India, and our Colonies secured £40,000,000 of trade, as compared with £17,500,000 which went to the rest of the world. Great Britain direct figured for rather more than one-fifth of the £40,000,000; but Hong Kong, which is a British colony, had a total trade with China of £24,000,000, and India a turnover of more than £4,000,000. Our principal foreign competitors were Japan, Europe (except Russia), and the United States, each of which do a trade with China slightly exceeding; or in the case of America a little below, the Indian total. Russia's share amounts to something under £3,000,000 per annum.

To this country China exported tea valued at £1,120,000 in 1896; silk, about £480,000; skins and furs of all kinds, £450,000; and straw for plaiting purposes, £350,000. The total quality and value of the tea exported showed a decline on each of the seven years preceding 1876, and this year it will probably show a still further decline, but the year 1899 may mark a new era in the tea trade of China. Not only are the Chinese determined, if possible, to make a supreme effort to increase its volume, but they will receive the support of the authorities and of all who are interested in the expansion of the trade of China. The planters of India and Ceylon, who have won their present position in the tea markets of the world by their own push and energy, will still have to fight to retain their supremacy. They have never received any favour from official sources, and they are not likely to receive any now. They will have to contend with keener opposition than they have yet experienced from tea growers in China and Japan, but we do not doubt that they will prove equal to the occasion. If China is to buy our goods in much larger quantities, as British manufacturers hope and expect, she must produce something in larger quantities to sell to us. As the Chinese will do their best to increase the output of tea and the demand for it in the West, their competitors in India and Ceylon will, therefore, be fully occupied in meeting this competition. Never was there a time in the history of the tea trade where economic methods and the employment of the best resources of enterprise and machinery were more needed.

LETTERS TO THE EDITOR.

SOME LEGUME QUERIES.

Sir,—I shall be glad if you or any of your readers could tell me where is the best place to get the seed of the "White Mustard," also how much it would take to do an acre of coffee with it and what price it is.

I tried gram (koolty) last monsoon with, I think, good results, and would like to try white mustard if not too expensive.

Can you tell me what the "Moth" or "Math" is which the Editor of the *Field* recommends, also its Hindustani name or Canarese name.

I enclose you an article which a brother planter had sent him from home, and which you see was copied from the *Journal of the Royal Agricultural Society of England*, and I take the liberty of forwarding it to you (my brother planter having since gone home, but previously giving me leave to do so), and in case of your not having seen it before may think it of sufficient interest to insert in your paper. Any correspondence which might arise from your doing so might be interesting and of value.

E. N. Leslie.

Kulsapore Estate, Koppa,
Kadure District, Mysore,
18*th March* 1898.

[We shall read the article in question, but fear that, owing to the leguminous question having been so exhaustively discussed during the last two years in these columns, there will be little new to cull from it.—Ed.]

DOMESTIC OCCURRENCE.

Birth.

Norman.—On the 15th March, at Lansdowne Cottage, Ootacamund, the wife of R. deR. Norman, of a son.

GENERAL ARTICLES.

CULTIVATION OF PARA RUBBER.

Para rubber (*Hevea braziliensis*) is now generally rec nised as the most profitable variety to cultivate. T greatest disadvantage entailed in its culture lies in elevation and situation of the soil required, *i.e.*, low lyi deep, damp lands. Some 200,000 plants from 1 to years are growing in various parts of Ceylon; th represent a total area of about 750 acres. Mr. Wil Director of the Royal Botanic Gardens of Ceylon, writes

Cultivation.

Hevea forms a moderately tall tree, not very much branched. begins to flower at about six years' old, but for planting purpo the seed of more mature trees (twelve or more years old) is prefera

About February, in Ceylon, the leaves mostly turn brown a drop off, and the flowers soon afterwards appear. They are follow by large woody fruits, each containing three seeds, which ripen July and August. The fruits open explosively, usually in the l part of the day and scatter the seeds to some distance. The seed very large, weighing about half an ounce. It has a hard seed c and the interior substance is very oily.

The seed soon loses its power of germination and ought to sown within a week of its falling from the tree. If it has to be s on a voyage of more than a week, it should be very carefully pack in charcoal. Even thus, however, the majority of seeds soon d and the only satisfactory way of sending seeds to distant countr is to plant them in soil in a Wardian case and allow them to gr on the way.

The germination of the seed is very rapid, and a long tap root soon produced. The seed should be sown about an inch deep well-prepared soil, in nurseries, or, if preferred, in bamboo pots baskets. They should be kept shaded and watered, and when t young plants are from 18 in. to 24 in. high, they may be plant out. Good results are also obtained by stumping, the plants bei allowed to grow about 3 ft. bigh, then taken up, and the main r cut across about a foot below the ground; but the method of pla ing out the smaller seedlings is perhaps preferable.

The plant may also be propagated by cuttings. The meth employed in the Botanic Gardens has usually been to take cuttin near the ends of the branches, but further back than any of t leaves. Each cutting is about a foot long, and as thick as a le pencil, and is cut off at both ends by oblique cuts made just bel leaf scars. The cuttings are planted in nurseries in wet ear This method is somewhat precarious; sometimes nearly all the cuttin grow, at other times only a small proportion.

The seedlings, stumps, or cuttings should be planted out duri rainy weather in prepared places. Holes should be dug as in t case of cacao, and filled with good soil. A little manure will oft be advantageous. The young plants require to be lightly shad for a time until they are established, and probably for the first t or three years they will grow the better for a certain amount shade, such as would be given by narrow belts of trees runni through the plantation. These belts should be arranged to act

id belts, as the *Hevea* is easily injured by wind. By the time the es are about three years' old they will have grown up to a height about 25 ft. or 30 ft. and form their own shade.

Various distances apart have been tried in planting *Hevea*. The inger plantation at Henaratgoda Garden has the trees planted ft. apart. Their average girth is now about 30 in. and they re- re thinning. It will not do, however, to conclude from this, as is netimes, that the trees should be originally planted more than ft. apart. On the contrary, the best results have been obtained planting 8 or 10 ft. apart each way. The trees thus form their n shade and keep down weeds, and a process of natural selection the best trees goes on, and the more weakly and dwarfed trees y be gradually thinned out in subsequent years. Another vantage of close planting is that the trees grow up straight thout forming many branches low down, and this very greatly ilitates tapping.

Para rubber is a surface-feeding tree, and catch crops should not erefore be grown between the trees, which require all the nourish- ent that the soil can afford.

The young plants are greedily eaten by cattle, deer, hares, and ner animals, and require careful protection for about eighteen nths, after which time they are generally tall enough to require t little further protection.

Weeding is also required for the first year or two, but afterwards e trees form a dense shade under which but few weeds grow.

The comparatively superficial growth of the roots renders manur- g easy, and it would probably be found advantageous in poor or ndy soils.

TERRACING AND DRAINING.

A DISCUSSION has been going on in your columns lately *nent* the advantages of terracing as compared with drain- ng. I am not satisfied that by making terraces, drains can e dispensed with. On the contrary, it appears to me that, where terraces are made, drains become an absolute neces- ity, otherwise wash and "scouring" would be tremendous, or in a heavy downpour of rain the water is bound to ac- umulate rapidly on the surface of the terraces, there being o outlet for it below, and no one need be told of the result hen that happens.

It is the experience of most planters that wash is greatest here water accumulating on roads and building sites, and ot being provided with the means of running away harm- essly into the ravines, rushes down the slopes. If the erraces were made at a gradient, they would act as drains; nd only imagine what the result of that would be? Why, ons upon tons of the best soil would be swept away, never o be replaced. What is required to reduce wash to a mini- mum is to make the soil absorbent to as great a degree as possible, and this cannot be done by mere digging: *subsoil* drains must also be provided. Make terraces by all means, too, if funds permit, but put in deep drains also, otherwise, I am afraid, the object of making terraces would be defeated. Covered drains would be the most advantageous if feasible, as in the case of deep open drains the sides are apt to cave in and block them; and besides that, they are a means of carrying some valuable soil away. The objection to covered drains is the certainty that they will get stopped up by the roots of the shade trees.

I will endeavour in this paper to show how covered drains *plus* terraces are feasible; but let me state at the outset that my plan can only be carried out in opening new land. First then as regards the terraces: I think they should be made as nearly parallel as possible to one another, and should run at a slight gradient down towards the ravines, or, where there are no ravines, to main drains, which should be provided. To effect both, it is necessary to bring the road or ghaut tracer into requisition. Start at the top tracing down at an easy gradient across the face of the hill and peg the trace out. The next trace start exactly 5ft. from the first peg. This distance, perhaps, wouldn't be maintained all along between the two traces; small tongues or "promontories" of land pitting out might perhaps throw the lower trace further out, but it wouldn't be much, and the terraces at these spots might be widened to receive two plants instead of one. Now, I don't propose that the terraces should be cut like dug-out roads, and then that they should be drained like roads and finally that pits should be dug in them to receive the plants. All this would be too costly. The plan I would propose—and I think it will strike your planting readers as exceedingly simple and quite within the bounds of practical planting—is simply this:—

After tracing the terraces and pegging them out, set coolies to work, commencing at the top of the hill, to cut drains 2ft. wide × 1½ deep on the lower side inside the pegs along the whole course of the terraces and opening into ravines or main drains. The soil excavated from the drain should be carefully piled upon the lower side like a protecting wall or bund. This will bring up the depth on the lower to about the same as it is on the upper side, viz., 2ft. The next thing to do is to fill the bottom of the trenches to the depth of a few inches with small stones where available in sufficient quantities, or, where they are not procurable, with dry sticks and twigs. Next fill up the trenches with soil, and in doing so have the ground above cut into so as to get the formation of a step. Now bring the lining rope into requisition and have the pegs placed in the covered trenches to indicate where the plants are to be planted. The only objection to my plan is that the lines of coffee can only be got straight up and down the hills; but this is immaterial so long as one knows the land is planted with the right number of plants. But see what an im-

mense saving there will be of soil; and note also that here is a way open out to us of practically killing three birds with one stone; for the necessity of making pits to receive the plants is dispensed with, and we have drains and terraces all made by one operation as it were. But the sticks and twigs would only serve to keep the drains open for a year perhaps, and then it would be necessary to make fresh drains on the inner sides of the terraces. These needn't be made wide; 9 inches at the outside would be enough, and they ought to be filled in the same way, that is with sticks and twigs at the bottom and soil above. This will not be costly as, if necessary, digging up the surfaces of the terraces can be dispensed with that season, and it would all go into "the day's work." Every succeeding season, if the drains are reopened—as they must be to keep them free of roots, &c.—after the rain has rendered the ground soft, the cost will not be great. In calculating cost, remember that a cooly can make 25 renovation pits, each measuring 3ft. × 2ft. × 1½, and don't forget that pits to receive the plants are dispensed with, and that digging may be dispensed with the first and second seasons, as the loose soil over the covered drains would keep absorbent for a good time without the aid of digging.

SOUTH MYSORE PLANTERS' ASSOCIATION.

The Annual General Meeting was held in Belur on 3rd M Present:—Messrs. J. Aird, R. A. Anderson, H. P. Cobb, J. Crawford, W. L. Crawford, W. M. Daly, F. M. Hamilton, Hamilton (*President*), J. A. Harris, (*Hony. Secy.*) C. Lake, L. S. Sladden, J. L. Stewart, M. J. Woodbridge, and A. Nich (*Visitor*).

The notice calling the meeting was read, the proceedings o last General Meeting confirmed, and the Honorary Secretary's re as detailed below, was taken as read:—

ANNUAL REPORT, 1897-98.

Gentlemen,—In placing this report in your hands, it is with ex regret that I have to record that crops have, with few exceptions, little if any better than last year. I am happy to state, however, that disease has not been prevalent to any extent, and the season so far h been more normal than was the case the last two years, prospects be said to be favourable.

Report of the S. I. P. E. C.—No intimation has yet been received Government. No doubt more urgent matters have delayed its rece consideration.

U. P. A. S. I.—A full report of the business of the year and o general meeting appears in the Book of Proceedings. A new feature the proposed allotment of funds to scientific investigation. I regr say, however, that the scheme for the employment of an **Agricult Chemist** has practically fallen through for want of support. Th the more to be regretted, as from enquiries made it appears tha project would not have involved so large an expenditure as was a pated, and had only three or four Associations come forward with offe help, it might have been carried through. The North Mysore Associ at the Dusserah urged the Durbar to engage an Agricultural Chemi attend to the requirements of the whole province. The proposal favourably received, and I believe they are making enquiries regardin engagement of a suitable man.

The Currency Question.—The persistent efforts of the Governm of India to bolster up the value of the rupee to nearly double its intr worth is a source of great anxiety to producers. The new gold Note and the remarks of the Finance Minister, show plainly their determin to keep up the rate of exchange, and indicate the possible introduc later on of a gold standard. With regard to the U.P.A. proposed cir letter, this Association, while it agreed that it was advisable to hold sultation with the Chambers of Commerce, Banks and other Merca institutions, deprecated the adoption of a definite policy and recour any action until the views of such bodies were ascertained.

Roads and Communications.—*Railways.*—The projected Rail from Arsikerri to the West Coast is still under the contemplation of Durbar, who are carefully investigating the best and most econom method by which the descent of the ghaut may be accomplished. *Roa* I have much pleasure in expressing appreciation of the work don the Executive Engineers and Messrs. Rice and Davy, which has resu generally speaking, in a marked improvement in the roads throug the Mulnaad. It is noticeable, however, that while greater attenti being paid to minor roads, some of the main routes, for instance Hassa Chickmaglur and Banawar to Belur, are falling into a state of disre It is satisfactory to note that soundings are being taken for the A bridge, and that operations are expected to be put in hand after the mons The Bage-Belur road, tenders for the repair of which were invited s months ago, is, I hear, still *in statu quo*, but I have reason to believ will be thoroughly put in order before the rains. The abandonment of work at the Chickanhully end of the Chickan-hully-Saklaspur road is to severe criticism. The D. P. W. fully recognise the utility of the r but owing to a few landholders, through whose property the trace pa having demanded exorbitant compensation, work has been stopped,

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

e expenditure of several thousands of rupees rendered useless. I have ged the matter being settled promptly by arbitration and a speedy re-mption of the work.

Post Office.—I have heard frequent complaints regarding the loss of ters, parcels, &c., and have laid specific cases before the authorities, but no instance were the missing articles found.

Police.—I am glad to notice that Government have raised the pay of ffadars, but judging by the class of men that are attracted to the force, fear that the remuneration of all grades is insufficient. My attention has en drawn to the neglect on the part of the Police to visit the coffee tates during the picking seasons, and my complaints to those in authority ve not always been taken notice of. No coffee-stealing cases have been ported to me, but there is no doubt that petty pilfering is as rife as ever.

Cardamoms.—The crop this season has been better than last, but rices are now lower. I have expressed our thanks to Government for ttling the re-assessment question.

Epidemics.—I rejoice that the plague has so far not reached this province, id trust we may escape it. I have drawn the attention of the Civil urgeon to the outbreaks of cholera in the Mulnaad, which now appear o occur annually, and suggested an addition to the staff of Hospital Assis-nts at times when the epidemic may be expected, the establishment of few more dispensaries, and an assured supply of the necessary medicines.

Labour has again been plentiful, and is, I think, likely to be so during he coming year; the scale of advances has already been reduced, and I hink a combined effort should be made to lower the rate of wages.

Sanderson Memorial Ward was opened in September last by the Deputy Commissioner of Kadur, and is now ready to receive patients.

Members.—Messrs. Egerton, E. P. Lake, Limouzin and Playford have eft, and Messrs. Gowans, Taylor and H. G. Harris have joined the Association, so our numbers are one less than last year.

Local Officials.—A constant shuffling of the minor officials, though possibly a desirable policy, causes great inconvenience, especially when in he case of amildars the incoming magistrate is not invested with 2nd class powers. Long periods not infrequently elapse before such powers are given, which might very easily be curtailed. I hear Kalsa is to be taken out of the Mudigiri taluk, and a new taluk formed with headquarters at Balehonnur. This will be a great relief to the Mudigiri officials.

Chaplain for the Planting Districts.—I beg to draw your attention to a letter I received from the Bishop of Madras, and request you will give the matter your careful consideration.

Funds.—It will be remembered that at our last meeting we agreed upon a sliding tonnage assessment as a means of raising the funds we require, which unless we pass a new rule will be in force the coming year. I myself, having in view the two past seasons, have reluctantly come to the conclusion that a crop assessment is too precarious a method on which to depend for income, and I can see no other course than to adhere to an acreage assessment. The income we derive from the acreage assessment that was in force last year may be computed as follows :—

	Rs.
12 as. per 10 acre on 6,000 acres	450
Add 45 members at Rs. 10 per head subscription ...	450
Total income ...	900
I reckon ordinary annual expenditure at	550
which leaves a balance of estimated income over expenditure of	350

out of which the U. P. A. subscription has to be paid.

The U.P.A. subscription is now assessed at a minimum of one anna per acre on a quarter of the cultivated area represented by members of the District Associations, and a maximum of one anna per acre on total area. Our total cultivated area (including cardamoms) is 17,500 acres, so that in round numbers the minimum we can pay is Rs. 275 and the maximum Rs. 1,1.00 I take it that we would like to pay something between these two. I propose, therefore, that we annul the crop assessment rule passed last year, that we continue the acreage assessment at 12 as. per 10 acre cultivated, and that we pay the U. P. A. Rs. 400, which will entitle us to 40 votes. When all 1897-98 subscriptions are paid, I expect to have a balance in hand of about Rs. 600. I have already paid the U. P. A. Rs. 100, and if we pay as I propse Rs. 300 more, we should have a balance in hand of Rs. 3 to carry forward.

Accounts are on the table, and show a balance in hand of Rs. 442-13-0. I greatly regretted to notice that the health of the Dewan had necessitated his going away for change, and trust he has returned so thoroughly restored that he will be able for many years to conduct the affairs of the State with his accustomed vigour and judgment. In conclusion, I will briefly refer to the lamented deaths of Mr. W. A. Allardice and Mr. D. T. Brett. The former was for several years President of the Parent Planters' Association of Mysore and the latter of the North Mysore Association. Both were highly respected, and their deaths are deplored by all Europeans in the planting districts of Mysore. Placing the resignation of my office in your hands,

I remain, Gentlemen, Your most obedient servant,

J. A. HARRIS, *Hony. Secretary.*

Leaf Disease.—Mr. J. L. Stewart spoke as follows: "Gentlemen, I have an explanation to ask for and a few words to say about a very injudicious and pessimistic speech made by one of our delegates, Mr. Harris, at the U. P. A. Meeting last year. This speech has caused an unnecessary small panic among agents, and consequently been the cause of much trouble and annoyance to men who depend on agents for money to work their estates. I use the word unnecessary advisedly, as after nearly twenty years' experience of coffee, I can honestly say that I consider that leaf-disease is no more virulent now than it was when I first came out to this country. Leaf-disease is a bogey very easily exorcised, and is made practically harmless by liberal manuring and cultivation. So long as a man does his estate well, he need never fear leaf-disease, but we cannot fight against providence, and I put down the last two years' bad crops entirely to the seasons; both the last two seem to have gone wrong altogether. If Mr. Harris had confined his remarks to this, the real reason of short crops, no harm would have been done. I think now we may congratulate ourselves, as I have never seen coffee looking better, nor with a better promise than it has this year. I will now ask Mr. Harris on what grounds he made the injudicious and alarmist speech referred to; and why he persisted that leaf-disease was going to ruin us in the face of reassuring statements made by other delegates."

Mr. Harris replied: "Gentlemen, I find it hard to believe in the sincerity of Mr. Stewart's remarks. If he considered that my speech would have such deleterious effects as he has described, why did he not at once denounce it? instead of waiting six months when the mischief, if any, would be done. If he believed in the opinions he has expressed, I say it was his bounden duty to the planting community to publish them far and wide. His not having done so leads me to suppose that his motives now are not serious but frivolous. As, however, there may be some who may consider that my description of the coffee industry was too severe, I would like to address a few remarks to the meeting. I will read the sentences which contain the description referred to: 'The coffee industry, at all events as regards the province of Mysore, is in my opinion, at the present time, passing through a crisis. Few of us are working virgin land, and the distinctly increased debility of our trees, both young and old, manifested by their less successful contention with leaf-disease, seems to indicate exhaustion of soil.' In the first place I would like to express my sincere regret if any member of the planting community has experienced inconvenience through a certain unexpected notoriety having been given to my speech, but I would ask you to remember that the ill-effects of leaf-disease will be found out in 'the Lane' and elsewhere without such adventitious aid as a speech at the U. P. A. Meeting; short crops, light and inferior beans tell their own tale. In the second place I assert, and I assert emphatically, that the words quoted above were in no manner too strong, and I maintain that they were in no degree injudicious, for I feel assured that the temporary inconvenience which some may have experienced (and which they would have experienced whether my speech had been made or not) is a small matter compared with the good that would have resulted had the scheme of employing an Agricultural Chemist been carried out. When I made my speech in Bangalore, we had just emerged from the worst attack of leaf-disease that has probably ever been experienced, which to my mind, as I said then, seemed to indicate exhaustion of soil. This by no means implied, as seems to have been interpreted by Mr. Stewart and others, that the soil was played out, that the industry was doomed! but merely that it required tonics, just as a man does after sickness, to restore it. The severity of the disease made the moment opportune for suggesting remedies. I hoped that the debate in Bangalore would elucidate matters, and that a scheme would be evolved that would permanently benefit us. This scheme has temporarily fallen through, but the discussion that took place is bearing fruit. A group of Nilgiri planters have, I hear, engaged a chemist on their own account, the Mysore Government are favourably contemplating a proposal to engage one to work in this province, and last, but not least, the attention of the whole planting community has been concentrated on the subject. So far then from my speech having been injudicious and pessimistic, as described by Mr. Stewart, I maintain that it was the

humble means of producing a most interesting discussion at the Conference in Bangalore, which I firmly believe will result in more enlightened methods of cultivation, and, mark you, a consequently increased credit in the coffee industry. I assure you, gentlemen, that I have the interests of the whole planting community at heart, and it would be a sincere grief to me were I to cause any injury to our undertakings. I believe myself that by judicious manuring and careful cultivation we shall successfully contend with the ravages of leaf-disease. We have two things in our favour as compared with Ceylon, a climate subject to long droughts, and a certain isolation as regards the position of our estates. The present season bears out this opinion: leaf-disease has been present in a very mild form, and prospects may be said to be decidedly favourable." The discussion then closed.

Roads and Communications.—Mr. Woodbridge proposed, and Mr. Daly seconded, "that steps be taken to insure proper arrangements being made for the ferry service at the Anjur crossing, and to put the approaches in order before the monsoon." Carried.

Messrs. Stewart, Cobb and Woodbridge testified to the frequent loss of articles in the Post Office and to the futility of laying complaints before the authorities. The following resolution was proposed and carried: "That this Association regrets that no serious notice is taken by the superior officials of the department of complaints laid against their subordinates, and is of opinion that many of the losses and irregularities which cause so much annoyance are due to the employment of incompetent and underpaid men, especially in the minor offices. This was carried unanimously.

Police.—Mr. Cobb expressed approval of the Honorary Secretary's remarks under this heading, and proposed a resolution to this effect, which was seconded by Mr. Woodbridge and carried.

Epidemics.—Mr. Stewart proposed, and Mr. J. G. H. Crawford seconded, "that as a temporary measure, till more dispensaries are established, that Government be asked to appoint Sub-Assistant Surgeons to visit certain localities at times when outbreaks of cholera may be expected; and that the Hon. Sec. intimate to the Senior Surgeon that some members of the Association will be willing to give such officers house-room for themselves and safe storage for medicines." Carried.

Mr. J. G. Hamilton having enquired whether it was not a fact that outbreaks of cholera almost invariably started in Hosmane, Chickmaglur, or in the quarter inhabited by low-class Mahomedans, Mr. Stewart emphatically condemned Hosmane as a hotbed of filth and disease, and suggested its destruction and the reservation of the whole of that portion of the town for the building of residences for respectable inhabitants, such accommodation having been much sought after of recent years. The Mahomedan quarter near the market and shanti was also mentioned as a source of danger. A resolution to the effect that the Honorary Secretary be requested to confer with the Chairman of the Municipality regarding the above suggestions was put and carried.

Sanderson Memorial Ward.—The Honorary Secretary informed the meeting that the proposed rules that the ward should be for the exclusive use of Europeans resident in the district, and that the governing body should consist of the Deputy Commissioner, the medical officer in charge of the district, and one planter to be elected annually by the subscribers, had received the sanction of Government. This was noted with satisfaction.

Labour.—Mr. F. M. Hamilton said: "With the export tax of from 25% to 60%, according to circumstances, forced upon us by that unjust steward, the Government of India; with a reduced price for our staple and an increasing number of competitors subsidised by the aforesaid unjust steward, who has written down their practical debts to us by one-half or one-fourth; with also an increased expenditure on manure (which being mostly country stuff is rendered no cheaper) made necessary by natural causes, by old age, and fair wear and tear; and with losses caused by defaulters, we have reached the vanishing point of profit or even living wage. As apparently no help is to be looked for from Government, our only resource is to shift a portion of our burden on to shoulders which can ill bear it. The country was reaching a position of respectable independence by our help, but the Government of India has shifted its burden on to the shoulders of the poor ryots, and we must do the same, having a noble example to follow. Advances we have already been able to reduce, as none of us can afford to employ a sufficient number of coolies to do our full routine of work, so there can be no chance of competition. This is not enough: we must also reduce wages. To do this, of course unanimous action is necessary. We know t the native planters are ready to join us, and it remains for us to the terms for this district if we can combine. Local combinat however, can do no more than reduce the wages of local perhaps South Canara and Lombani coolies, as these classes, w the exception of South Canara coolies, are confined to Mysore. regards Ghaut coolies, there are so many to whom it is so absolut necessary to work that I do not think our reducing the wages wo affect the supply appreciably. It is for these three classes alone t I propose immediate reduction, but I think the time has arri when the Mysore, Coorg, Wynaad, and Nilgiri Associations sho combine to reduce wages of all Canarese and Tamil labour, an therefore hope you will carry both the following resolutions, something on similar lines: (1) that members of this Association bind themselves to pay no more than 3 annas per day for local, Sou Canara and Lombani men, or more than 2 annas for women of t same classes; that they also bind themselves to reduce the wages all maistries who are receiving more than Rs. 10 pay by 25%, a all those who are receiving more than Rs. 8 by 10%, and furth bind themselves to give no direct compensation; (2) that the Ho rary Secretary be requested to put himself in communication, throu the U. P. A. S. I., with those Associations using the same labour ourselves with a view to securing the same reduction in Maid Country and Tamil labour."

I personally would like commission reduced, but I am given understand that this would be objected to, as commission even the worst times was never less than it is now. Anyhow, I think might bind ourselves not to pay more than the present 5% for lo labour.

Mr. Stewart took exception to the pessimistic tenour of M Hamilton's speech, and trusted he would withdraw the expressi "vanishing point." He declined to bind himself in any way, ev as regards local labour, which being specially skilled in certain wor is worth the full wage.

Mr. W. L. Crawford considered the time inopportune for d cussing the subject of labour, as the report of the Committee Enquiry was still under the consideration of Government, and th before any change of rates was made, it was advisable to know wh new legislation was likely to be put in force.

Mr. Aird said he thought it was useless to continue the discussi as there was no likelihood of unanimity, which was absolute necessary.

Mr. Harris said he thought it was premature to bring forward scheme for the general reduction of wages, but thought that grou of estates might combine with a view to reducing the local rate of pa

Mr. Hamilton's motions were negatived.

Local Officials.—Mr. Stuart proposed, and Mr. Woodbrid seconded, that this Association wishes to emphasise the remarks the Honorary Secretary under the above heading in his report, and invite the attention of Government to the importance of the talu of Mudigiri and Belur, which entitles them to be served by high-cla officials.

Chaplain.—The Honorary Secretary was requested to convey the Bishop this Association's appreciation of the courteous and kind interest he had displayed in wishing to establish a clergyman in th planting districts, and to express its extreme regret that as far this portion of the community is concerned, the numbers are too fe to admit of an appreciable amount being raised towards the requir income.

Funds.—The proposal in the Honorary Secretary's report w adopted.

Proposed Game Act.—Messrs. Graham Anderson, Park, and Hunt were appointed to form a Sub-Committee to consider the Ac and submit proposals to Government.

General Meeting.—It was resolved that this shall in future held in Sacklaspur, and that its duration shall be decided by th Committee.

Rules.—Resolved that the President and Honorary Secretary *ex-officio* delegates to the U. P. A. Meeting.

Election of Office-bearers.—Messrs. J. G. Hamilton and J. A. Harr were re-elected President and Honorary Secretary; Messrs. L. Craw ford, G. Horne, J. G. Hamilton, J. A. Harris and W. H. Scott wer elected to form the Committee, and Messrs. Graham Anderso

[. Playfair and W. H. Scott as extra delegates to the U. P. A. A
of thanks to the officials for the past year closed the proceedings.

J. A. HARRIS, *Hony. Secretary.*

NORTH MYSORE.

'ROCEEDINGS of the Annual General Meeting of the North Mysore nters' Association held at the Club, Balihonur, February 28th, 8. PRESENT:—Messrs. F. Clifford, H. G. Bonner, L. Colledge, H. rthey, C. Browne, E. C. Bolton, C. Crawford, L. King Church, A. ster, W. H. Maynard, N. Seton, H. Pilkington, C. Harvey, H. gington, F. J. Parton, *Hony. Secretary.* Visitor: G. Horne. Mr. F. fford, in the absence of Mr. Scot-Skirving, took the chair.

The accounts for the year were audited and passed by Messrs. H. kington and R. G. Upton.

The Honorary Secretary then read the annual report as follows:—

Annual Report.—Gentlemen,—Your Committee have much easure in laying before you the annual report for the year now ding.

Accounts.—In spite of the fact that one of the largest proprietors s withdrawn his estates from the roll of the Association, the in- me has been sufficient to pay our expenses and leave the Reserve und of Rs. 1,000 intact. The number of estates now subscribing to e Association is 59. It is with deep regret that we have to record e deaths of Messrs. Brett, W. Allardice, Sen. McMaster and Lee uring the year under review.

Roads.—We are glad to say that on the whole the roads in the oppa District have been kept in better condition during the past ear, chiefly owing to the efforts of our energetic District Engineer Shimoga. This, however, cannot be said of the Balihonur-Aldur oad, the condition of which is very bad. Many of the culverts hich were damaged during the last monsoon are still unrepaired, nd we would once more urge the Government to make a large llowance for the upkeep of roads in the Mulnaad, and make arrange- ents for the closer supervision. We have to express our appreciation the energetic and rapid progress made in the construction of the ababooden Hill Road to a point (*viz.*, the Kesinourthy Estate), but the same time regret, in spite of repeated representations, abso- tely nothing has been done towards carrying out the easiest, least xpensive, and most used portion of the road (*viz.*, between Kulhut- pore and Lingadhully, a distance of not more than 4 or 5 miles; is portion is the outlet of the Bababooden Road on this side, and lso the only outlet for the following estates, Muskulmurdee, Sumpi- ay, Sumpigayhutty, Kurkulmutty, Doopatkhan, Lall Bagh, Shigay- han, Jignykhan (2) Doopat girry, Tekhan (2) Sidakhan, and Wany owda's Totas Kullay Gowda's Kesinvurthy, Kulhutty and Thair- iddykhan, which is at present only a track, passable in the dry eather, but next to impassable in the rains, and we may also add rom Kulhuttipore to Hebbay there are nothing but tracks, although ome of the finest estates in Mysore lie in this direction, and we most trongly urge the Chief Engineer to the necessity of carrying out he completion of this outlet before the coming South-West Monsoon, nd also sanction a road from Kulhuttipore to Hebbay for reasons given above, which may also benefit Government in opening out the outhern portion of the Luckwalli Forest. We beg to point out the leplorable condition of the Santaveri Chickmuglore and Lingad- ully Birur Roads. About two years ago Mr. Oliver was requested by he Executive Engineer to take up contracts on the former road as the Ex. Engineer admitted, he was absolutely unable to obtain labour to maintain and keep in repair the road in question), and was assured before the "Local Fund Board" that there would be no difficulty as to payments for work done, or interference from petty officials. Under these circumstances, Mr. Oliver induced two gentlemen to take up 6 or 7 miles of worst and ghaut portion of this road. The state of the road was thereby greatly improved, but, owing to the difficulties with reference to payments, &c., these gentlemen have absolutely refused to continue their contracts. The Tadsa Bridge is progressing favourably, but is not likely to be opened for traffic before the beginning of next year. We regret that the work on the Shimoga Railway has not been pushed on as quickly as we anticipated, the first section of which is unlikely to be in working order before next December. The new Katcherry building at Koppa is, we understand, shortly to be commenced.

Baggani Toddy Trees.—The objectionable Memorandum, No. 215, issued by the Excise Supervisor last October, relating to toddy drawing on Coffee estates, has, on account of the protests raised by the Association, been cancelled in the Malnaad, until the end of the current official year.

Agricultural Chemist.—The Mysore Government, through the Dewan, has expressed its intention of providing an Agricultural Chemist for the Province. The matter is, at present, under the consideration of Dr. Evans, head of the Geological Department, who has kindly undertaken the difficult task of selecting a competent man.

Scale Pests.—Although we are not at present afflicted with the green bug, your Committee are pleased to announce that sufficient funds have been collected to send Mr. H.O. Newport of the Lower Pulneys to Australia to bring over a consignment of lady-birds, with which it is hoped that the pest may be eventually exterminated.

Coffee Stealing.—In connection with the Hattan Kodigi case, a reward of one hundred rupees has been paid to the Police. We still have to deplore the fact that coffee stealing has not in any way decreased, and regret that the Police do not take advantage of the powers they have, more especially in examining the books of small dealers in coffee.

The South of India Planters' Committee.—With reference to the report of the Enquiry Committee, we trust that now the fear of famine is over, and the troubles on the frontier are within measurable distance of suppression, that the Supreme Government will find time to consider the report of the Commission.

Manures.—We much regret that Government has made no move in reference to the removal of the import duty on manures, but we hope that when Government recognizes the crisis through which our industry is passing, that steps will be taken to relieve us from what is a direct tax on our industry.

Dispensary.—We regret to say that the Dispensary at Santavari, which was sanctioned some time ago, has not as yet been established, and would point out to Government the urgent necessity of providing medical aid in that section of the Association. During the year three Committee Meetings have been held, the proceedings of which are laid on the table. We feel sure that you will join us in expressing regret that our Deputy Commissioner, Mr. Weir, is leaving us, and trust that he will enjoy a well-earned rest in England. Mr. Subba Row, the Amildar of Koppa, has taken up an appointment as Assistant Superintendent of Police at Chittaldroog. The loss the Koppa District has sustained is very great, for he always displayed the keenest interest in the planting industry, and was ever ready to render assistance to the community in general. Mr. F. S. Hay, who worked so hard as Honorary Secretary in the interests of this Association, has also left us to take service under the Mysore Government. You will join us cordially in wishing him every success in his new career. Mr. Frank Clifford, who has already done us such good service on the Local Fund Board, has kindly consented to continue his services, for which you will join us in expressing our thanks. In conclusion, we beg to place our resignation in your hands and ask you to proceed to the election of office bearers for the ensuing year.

FRED. PARTON, *Honorary Secretary.*

Mr. L. D. Colledge proposed, and Mr. C. Brown seconded, a cordial vote of thanks to Mr. Parton for the efficient way he had carried on the duties of Honorary Secretary for the past year.—*Carried nem. con.*

The Honorary Secretary then read a letter from Mr. O. Scot-Skirving, who was unable to attend owing to his departure for England:—

"Gentlemen,—I regret, beyond measure, my inability to attend the Annual Meeting of the N.M.P.A. When you meet together on the 28th, I shall be nearing England—you will understand that my departure prior to the Annual Meeting was a matter of necessity.

CENTRAL HOTEL,
INFANTRY ROAD, BANGALORE.
(Under English Management.)
The most comfortable and convenient for visitors.
TERMS MODERATE.

At the last Annual Meeting you did me the honor of electing me your President, and you will appreciate the keen disappointment I feel in being unable to be with you in person to give you an account of my stewardship during the past year, and will excuse the absence of the usual presidential address. Accept the message of regret and farewell which I send you from the train. The Annual Report which the Honorary Secretary will lay before you will, I am sure, ably explain the work which has been done during the past year. This I trust will be deemed satisfactory. In referring to matters other than the actual work of the Association, I fear we must look on this year as the most disastrous and unhappy one our community has ever experienced. Accompanying one year, generally speaking, of unexampled short crops and straightened circumstances to many of us, there has been death, sickness, and sorrow. Your sympathies will have gone without stint to those families who have suffered bereavement and are in sorrow. When you meet together on the 28th you will miss one who was the central figure and moving spirit of the Association as President, Member of the Committee and Honorary Secretary ever since he himself originated it, 17 or 18 years ago, one who never spared himself, but give the best of his time often at personal loss and inconvenience. Or the work of the Association, in referring to what Mr. Brett has done for our Association I need not remind you that to him is due, in great measure, if not entirely, the inception and formation of the United Planters' Association which has enabled the whole planting community of Southern India, as a collective body, to give expression to its needs in a force that is listened to by the Government of India. Gentlemen, the shock of Mr. Brett's sudden death came at a time when the cup of sorrow amongst our community was already full. Among other deaths, of which I will not remind you, was that of Mr. W. A. Allardice, who for years was a member of our Committee and who was formerly President of the original Mysore Planters' Association. In him the Association and the community, generally, lost, not only one of its oldest and most respected members, but one who was revered and honoured, whose life amongst us had been one of an uncompromising truth, and whose wise counsel will never cease to be missed. Gentlemen, I now tender you my resignation as President of your Association and bid you farewell." Mr. Leslie proposed a vote of thanks to Mr. O. Scot-Skirving for his services as President during the past year, and regretted the cause which had prevented his attendance at the meeting.

The Committee was then balloted for with the following result:—

Mr. E. C. Bolton—*President.*—MEMBERS:—Messrs. F. J. Parton, C. H. Browne, F. Clifford, W. H. Maynard, H. M. Northey and H. Pilkington.

Mr. Bolton returned thanks for the unexpected honour done him, and while regretting the absence of abler men to fill the position, assured the meeting that no efforts on his part would be wanting to merit the confidence placed in him.

Laid on the table letter from the Right Reverend the Lord Bishop of Madras *re* the appointment of a Clergyman for the Coffee Planting districts of Mysore. Resolved that while the Association thoroughly appreciated the kind interest displayed by His Lordship in the spiritual welfare of the planting community regretted that it could not officially support the proposal, but requests the Honorary Secretary to make enquiries as to the probable amount of voluntary contributions that might be forthcoming for this object.

In connection with the above, a letter was read from Mr. Maxwell Maynard which the meeting decided was also a matter for private enterprise.

Read letter from the President of the Local Fund Board in reference to the proposed tax of 1 or 2 annas to be levied on carts resorting to the Koppa Bazaar, the proceeds of which should be devoted to the cleaning and fencing of a general sanitation of the Koppa village.

Unanimously resolved that the Meeting strongly disapproves of any such tax being levied on carts resorting to the Koppa Bazaar, as it would tend to drive away the import of grain and other food supplies. This Meeting considers it the duty of the Municipal authorities to keep the Koppa village in a sanitary condition without the imposition of so objectionable a tax.

Agricultural Chemist.—Read letter from Mr. Maxwell Maynard. Resolved that the Honorary Secretary be requested to communicate again with the Mysore Government in the appointment of an Agricultural Chemist for the Province, urging the necessity of early action in the matter. Draft of Act for the protection of wild animals in Mysore territory.

Resolved that a Sub-Committee of the following gentlemen be formed:—Messrs. C. Browne, W. Maynard, L. King Church, H. kington and F. Parton, be formed to consider the proposed draf

After the usual vote of thanks to the Chairman and Hono Secretary, the meeting broke up.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (March 4, 1898) say Larger supplies have been brought forward in Public sale this week meeting a fair demand were mostly sold at previous values.

About 3,300 bags East India were offered and nearly all disposed steady prices whilst some favourite marks of Naidoobatum attracted competition and realised extreme rates.

Fine Costa Rica also met a good market at very full value but medium and inferior descriptions sold slowly at irregular to slig easier prices.

The terme market has been inactive with only a small business pas and quotations are practically unaltered since our last.

Our monthly statistics published to-day show an increase of 8050 in European stocks, and a reduction of 570 tons in the World's vis supply.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets the Week ending March 2nd, 1898, says:—Bank rate 3%. Bom Exchange closes at 1s. 4d. Brazil Exchange $6\frac{1}{16}$d. Rupee pa $3\frac{1}{2}$% $63\frac{5}{8}$. Silver $25\frac{3}{8}$d. per oz.

A quieter tone has prevailed in this market, the more important s plies of all kinds meeting with less competition. At the close the ton dull, and we quote a general decline of 1s to 2s per cwt., except for fin which continues very scarce. Brazil markets are quiet but steady.

The Dutch sale of 21,026 bales Java, 53 cases and 20 bales Padang, h in Rotterdam yesterday, went off with competition at an advance 1 to $1\frac{1}{2}$ cents. Good average Java is now quoted at 35 cents.

Daily receipts averaged 8,100 bags in Rio, and 11,300 bags in Santos.

Futures have ruled quiet, and close about 3d lower, viz.:—Good aver Santos in Havre, March delivery, fcs. 36.75, in Hamburg pf. $30\frac{1}{2}$, and N low ordinary Rio in New York $5.60.

To-day's London official quotations are:—

	March	May	July	Sept.	Dec., '9
SANTOS ...	30/-	30/3	30/9	31/-	31/6

We quote:—

Ceylon, mid. to good mid.	95/@107/	Costa Rica, mid. to fine...	77/ @1
Do. small to low mid.	80/ „ 93/	Do. ord. to low middling.	53/ „
East India, mid. to good mid...	77/ „ 93/	Jamaica, good to fine ord.	43/ „

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, ht Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including tage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for advertisements will be: 4 as. per line for the first, 3 as. for the second, 2 as. for the third and succeeding insertions. Five-line advertisements m Subscribers will be inserted for three issues for one rupee; non-Subibers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic urrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," lanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been moved to Madras, all remittances should be made payle to the Manager of *Planting Opinion*, 3, Esplanade ow, Madras, who will also attend to all advertisements, &c. Letters to the Editor should be addressed to Coonoor, usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 8th April, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

S. E. Wynaad.

DEVALA, 30*th March.*—*Weather.*—During the past four days it is very, very hot by day, and about every evening the clouds bank up and show every sign of rain, but the strong east wind follows and breaks up the clouds and causes the failure of rain. Yesterday evening we had a few drizzles which is worth nothing. *Crops.*—Spikes hold out still, but rain required soon to set. *General Health.*—Fever prevalent.

Nilgiris.

COONOOR, 30*th March.*—*Weather.*—Rain still holding off, though clouds are banking up persistently. A few showers would do wonders for the blossom already out on the lower totes, and also for the fine spike on the upper ones. Tea, too, wants rain badly. *Crops.*—Coffee not in yet on high estates, where picking will go on some months yet. On the whole the hills have done very fairly, and if this year's rains are favourable will do excellently for the 1898-99 crop. *General Health.*—Indifferent. *Labour.*—Ample as usual. *Interesting Item.*—Station filling up rapidly for the season.

KULLAKAMBY, 31*st March.*—*Weather.*—The clouds have been gathering for the last few days, and distant thunder heard, so rain cannot be far off. *Crops.*—Some blossom which came out early has been lost for want of rain; but on an average the amount is small, and if rain falls in a day or two, the spike promises a good crop. Pruning nearly completed on some estates, but the higher ones are still gathering a little crop. *General Health.*—Influenza rather frequent, and a little fever; otherwise health good. *Labour.*—Sufficient. *Interesting Item.*—A panther has been prowling about the neighbourhood, but so far has done no mischief beyond mauling a dog.

PLANTING IN THE MALAY STATES.

The first Annual Report of the United Planters' Association of the Federated Malay States contains matter of moment to all interested in coffee. Coffee in the Malay States is almost exclusively Liberian, for which the local conditions of soil, rainfall and temperature are most admirable. Bountiful crops can be obtained regularly to a degree unequalled, save, perhaps, in America. The prices, alas, of Liberian have fallen to almost the lowest depths of a low and falling market, though not quite so low as Rio and Santos. While the latter was selling at 23s. 6d., Malay Liberian fetched 32s. to 33s. at the same time. It is with these common varieties that are being produced in yearly increasing quantities that Liberian has to successfully compete, if the industry is to keep its head above water.

The Chairman of the Malay U. P. A., Mr. Hill, reckons that estates of 300 to 400 acres in full bearing and highly cultivated can be looked upon to produce a crop of 5½ to 6 piculs (6 to 7 cwt.) per acre at a cost of from 90 to 95 dollars per acre, with the coffee delivered in Singapore, representing roughly 3¼d. to 3½d. per lb. in London. Is there any country where coffee of a similar grade can be produced cheaper than this? The estimated cost of the largest Coffee Company in the world, the Dumont Co., is £40 per acre, and the time to bring it into full bearing is placed at five years. Mr. Hill points out that the difference in initial cost per acre is thus very great. If these figures held good for all South America, Malay planters would have very little to fear, but the capital cost of most of the Brazil plantations is, we understand, substantially less than that estimated by the Dumont Company. It is of the first importance that the actual cost of production be ascertained, as it will enable Malay to know what its chances really are.

In the meanwhile, Mr. Hill strongly urges that every effort should be made to bring the grower and producer into closer touch, and to do all that is possible to introduce Liberian coffee on its own merits to the public. The urgency of the matter may be appreciated when we point out that, according to Mr. Hill's figures, the cost of production fully equals the selling price in London, from which again brokerage and other charges must be deducted. So that, if we have understood Mr. Hill aright, Liberian coffee in the Malay States is very far from being a remunerative staple. The improvement in the labour supply is perhaps the solitary bright point in the report, though the President of the Malay U. P. A. adopts all through a far more confident and cheery tone than might be expected from our remarks. There are brighter days in store, we sincerely trust, for Malaya, and if Liberian coffee cannot be made to pay, it must be abandoned for Arabica, or better still for tea, ramie, rubber, camphor, or any of the other new products now demanding attention.

We note that this view has evidently, and none too soon, struck the planters themselves, and they have addressed Government on the subject of establishing experimental gardens.

NOTES.

Ceylon has exported 14¾ M. in January and Februa (22nd) compared with a very even output of 12½ to 12¾ during the preceding three years.

Tea Exports. The total sailings of Indian t from Calcutta for the eleven mont ending 28th February 1898 were over 146⅘ million pound compared with over 146 M. for the corresponding peri in 1897 and 133 in 1896. For America the figures a respectively, under 2½ M., over 2⅘ M., and over 1 M. F Australasia there is a slight increase over the two last yea *i.e.*, over 6½ M., as compared with 5⅘ and 6½ in 1897 a 1896 respectively. "Other places" show a total of ve nearly 5 M. against 6¼ and 4¾ M. the previous two yea Lastly, Great Britain took 132⅘ M. compared with 131 and 120¼ in 1897 and 1896.

"Pungent" Manures. In one of the last issues of t Calcutta *Planter* we notice a curiou written article on "Pungent Manures." According to t worthy writer, it seems that the intrinsic value of a manu is based on its smell! The writer, after saying "h wonderful it is to reflect upon the ignorance as to the co stituents of manures . . . . that has prevailed down to with a very recent period," straightway asserts that the act burning bones destroys their phosphates!

It is not often that our serious contemporary enlivens with gleams of humour, and we hope its staff will strengthened for many a long day to come by the pen the author of "Pungent Manures."

The Cacao Market. Prices, says the *Grocer* of 5th u still pursue a downward course, a are mostly 1*s.* to 2*s.* lower than they were last week, but fairly good demand prevails, and the bulk of the parc offered by auction has found buyers, the most attract portion being composed of 5,715 bags Grenada, which w at from 70*s.* to 77*s.* for common to fine, with poorer qualit at 65*s.* to 69*s.* per cwt. 3,420 bags Ceylon were about o third sold at 70*s.* to 78*s.* for ordinary to bold red, at 80*s.* 85*s.* for fine (bought in), at 60*s.* to 68*s.* for small and mix and at 49*s.* 6*d.* to 59*s.* for black and packings. The oth description in public sale appeared in much lighter quan ties, and passed the hammer as under:—445 bags Trinid at 70*s.* to 75*s.*; 220 bags Dominica at 69*s.* 6*d.* to 72*s.*; bags Jamaica at 67*s.* to 67*s.* 6*d.*; 103 bags Surinam at 7 89 bags Guayaquil at 76*s.*, and 78 bags Java at 62*s.* 6 but 120 bags Samana were retired at 75*s.* and 300 ba Venezuela at 85*s.* to 95*s.* per cwt. By private treaty business done includes Summer Ariba (Guayaquil) at 8 to 85*s.* and Ceylon at 72*s.* to 76*s.*

The Claridge transplanter. We have received a couple samples of these transplanters, wh seem to be excellent departures more ways than one. The practical trial to which we s mitted them induces us to offer a few remarks wh Mr. Claridge may possibly find of interest. For protrac use the transplanter seems too weak, but by adoptin shorter grade of tin, this fault could be easily remedi We should also advise a removable handle to be fixed

top of the transplanter, to enable the cylinder to be ssed easily into the earth without hurting the hand. e handle might be of wood, say a foot or nine inches g, and 4 to 6 inches broad by 1 inch thick. The centre uld cut out to allow a free passage to the stem of the nt, and the lower side grooved to fit the cylinder. In t weather it strikes us that there is a chance of the th-ball clinging to the side of the cylinder, and thus venting its removal. A "rammer" or two per every zen cylinders might prove very useful in such cases. With these changes Mr. Claridge's transplanter will, we nture to prophesy, turn out to be a most useful and luable little implement. By the way, we should much e to know where this new transplanter can be supplied olesale, and its price per 100 or 1,000.

---

mphor and coca plantations.

It is a little "previous" to suggest methods of treating a new product like camphor or coca for cropping rposes, but we do so for the benefit of the few owners no happen to possess individual plants. The crop in both ses is a leaf one, and it is, therefore, highly desirable that should be grown in such a way as to favour its increase d render its handling an easy matter. The simplest ethod that occurs to us would be to treat the plants, if possie, like tea, that is prune them down and pick the flushes. ithout actual experiment, it is of course impossible to say w they would stand the treatment, but as it has proved eminently successful with tea, it is certainly well worth ying. To forecast the course of the market, if either oduct were largely cultivated, is extremely difficult. But regards coca, the present yield is so great, close upon lf a million pounds, that any fears of flooding the market ay be abandoned for very many years to come. The ltivation of camphor is being so actively pursued, and in many parts of the world, that a more careful attitude ust be observed. In both cases, however, experimental ltivation could be carried on easily enough, and at a very ght expense on most coffee estates and a good many a-gardens The Curator of the Government Gardens, tacamund, should be able to meet a small demand for th these products.

---

e Moon and Vegetation.

A writer in our interesting contemporary, *Indian Gardening*, has a very emphatically written letter on lunar changes with regard to vegetation." He alleges ry strongly that the moon has a very powerful effect, deed, on vegetation, and goes so far as to label disbevers in his ideas as "mutton-heads." In proof of his contion, he brings foward the "experience of thousands," hich is of course conclusive.

There are one or two points which could easily be settled, for instance his assertions on timber-felling. His idea that the sap of plants rises and descends with the changes the moon. So that to coppice a plantation, the trees ould be felled when the moon is invisible, as "the whole its sap" is supposed to be in the stool. This is also the est time for felling trees for timber or fuel. If, on the ntrary, one wishes to utterly destroy all vestige of life in plantation, one need only, so "Luna" gravely informs us, oose a full-moon night to fell the trees. Bamboos are also luded to, as might be supposed. These should be cut at the wane of the moon. The gathering of crops should always take place under a three-quarter-full-moon, never a waning one. All root crops are lifted with a waning moon and planted with the same. Another curious superstition is connected with the plantain, which never grows properly if planted at the wrong time. Even flowers or ripe fruit are never gathered under a waning moon after sunset.

We shall be glad to hear from any of our correspondents who have personally (we do not care for third or fourth-rate evidence) investigated the matter.

Leaf Disease in Queensland.

Mr. Tryon, the Government Entomologist, of Queensland, referring to a telegram from Townsville, that the coffee leaf-disease is prevalent in the Russell district, says the department have officially dealt with this rumour months ago; and that in no case has he found any symptom of the disease in question. It has been whispered abroad for some time past that this dread scourge of the coffee planter had made its appearance in this district, but nothing of a definite nature is known yet as to its presence. When Mr. Tryon was in Cairns, it was reported that the disease occurred in more than one plantation, and he went to the trouble to travel to the Johnstone River, and examine all the coffee *en route*. On that occasion he could find no indication whatever of leaf-disease proper, though affections in the coffee plant were noticed, which might give colour to the suggestion that they were victimised by the notorious Ceylon disease. As a matter of fact, the department officially dealt with the rumour months ago, and the regret is that it should be revived and have been circulated to the extent it has. He is now engaged in investigating insect and fungus pests, and his enquiries have led him to examine nearly every coffee plantation in Queensland. Speaking generally, the Government Entomologist considers the coffee plant in this colony to be extremely healthy, and in no case has he seen any characteristic symptoms of the *Hemeleia vastatrix*. As he explains, wherever plants are cultivated, no matter what kind, they have some enemies, and coffee in Queensland is no exception to the rule.

Indian oranges for England.

The small percentage of our readers who have any faith in the latest possibilities of fruit-growing will be greatly interested in the following extract from *Indian Gardening*. There are few planting districts in South India where the orange will not grow to perfection with ordinary care. The difficulties experienced in the proper packing and transport of the ripe fruit to such a far distant market as London, great as they are, are not insurmountable. We hope our contemporary will give its special attention to such subjects as the best shape of crate to be used, the best method of "sweating" or seasoning the fruit in order to toughen the skin, and such kindred matters.

Messrs. W. Hutchinson and Co., a London firm, write as follows on the subject of Indian oranges for the London market:—

"It may, perhaps, interest some of your readers to know that in 1894-95 we received several consignments of oranges from the Central Provinces in India, and many who sampled them described them as the finest oranges they had ever tasted. The oranges were sold by us through a leading Covent Garden salesman, in some instances at as high a price as threepence each. It should be mentioned that they arrived at a time when oranges in this country are generally considered 'over.' But in spite of the high price realised, the venture,

presumably, was not, from the growers' point of view, a financial success, as the consignments have not been repeated. We think two causes alone were responsible for the failure of the experiment. First, the oranges had to come over as ordinary cargo, and a large number were pilfered *en route*. (We, who know the oranges, feel almost inclined to condone this offence!) And, next, owing to the want of proper accommodation, only a comparatively small portion of the consignment was fit for sale. Further, the shipper had great difficulty in getting any of the steamship companies to carry the consignments. We venture to think if proper freight accommodation for carrying fruit was provided by some of the steamship companies, as is the case with regard to Australia and America, a large and very profitable export trade in Indian fruits would be speedily created."

The London Market.

Coffee.—Larger supplies have been offered this week, says the *Produce Market Review* of 5th ultimo, and the demand has improved, although prices continue to show the same wide margin between the lower and fine grades. A decidedly lower range has been established for common and medium Costa Rica, and these qualities are now relatively cheap and should lead to a much larger business. The finer ones are, however, still comparatively scarce, and only come forward in such small quantities that prices are fully maintained. East India continues to sell freely for export, but the home demand is slow; the first of the new crop of Naidoobatum which has been sold this week should, however, alter this. The quality is quite equal to the standard of recent years, and although the bold fetched about the same prices as last year, the second size was from 12*s.* to 16*s.* lower. Of other kinds, Guatemala only sells slowly, but a better trade has been done in Salvador, of which description a much larger quantity has been sent than in any previous year. The terminal market has shown some fluctuations, but closes at about the same prices as last week.

Indian Teas.—The season has practically closed in Calcutta, the last public sale having been held there a week ago. This has imparted a stronger tone to the market, especially for the fine and finest descriptions, and it now seems quite probable that the supply of the finer teas will be more restricted during the next few months than appeared likely a short time since. Although there has already been a material advance from the lowest point in these grades, it is by no means improbable that values may mark a further important rise, as there is likely to be a gradually decreasing proportion of these kinds in future public sales here. The more useful medium sorts have shared in the upward movement, but not to the same extent as the finer teas, the rise being from ½*d.* to ¾*d.* as compared with the prices ruling at Christmas. Even at the advance it will be practically impossible to follow teas of the earliest crop, as most of the supplies now coming forward are deficient in quality, while the appearance of the leaf is also indifferent. The lo qualities, with few exceptions, are unchanged in value, as Calcutta advices indicate that a large proportion of later shipments will consist of common qualities, ther not likely to be any scarcity of these kinds. Compar the figures of the past month with those of February year, the imports are smaller by 629,000 lbs.; deliveries s a slight increase, *viz.*, 82,000 lbs., while the stock stand 64,080,000 lbs. against 55,424,000 lbs. At the public s 35,679 packages were brought forward, 4,465 of wh were withdrawn.

Experimental Gardens.

Unless the U. P. A. S. I. general, and its Nilgiri section particular, soon bestir themselves, even the present ap gies for experimental gardens on these hills will soon van The Ootacamund garden is already—in an experime sense—*non est*, the Gudalur garden is practically abando while the Burliar garden alone possesses vitality. A c plete system of botanical gardens could very easily be car out on the Nilgiris and Wynaad, for in these two distr we have samples of every variety of soil and climate to found on the Western Ghauts. Supposing a planter want plant up a new product of any kind, how is he to set abou at present? Where is he to get absolutely reliable infor tion as to its habits, the best conditions of soil, climate, e under which it should be grown? Echo answers, whe If a chain of gardens were established on the Nilgiris Wynaad, the information he wants could be easily gi from the living examples on the gardens. Let us giv short sketch of what we mean. To commence with, e garden need only be a few acres in extent, though at 20 acres at least should be reserved for future extens As we mentioned before, the Nilgiris and Wynaad c endless combinations of climate and soil. Kullar, at foot of the ghauts, offers a very good sample of a hot, climate. At Burliar, a few miles up, we get rather m rain, and the heat is many degrees less. A third gl garden at Glenmore, and a fourth at Coonoor itself co each have their distant uses. Then midway betw Coonoor and Ootacamund, and between Ootacamund Pykara, thence down to Gudalur, Devala and the W Coast. In the chain the rainfall would vary from ab 40 inches or less to over 200, with elevations from 1, to 7,000 feet. Some would have the South-West Mons in all its force, others the North-East, yet others ag would have a modicum of both. The gardens establish

MANAGER, ARIENKOW ESTATE,

Shencotta

a few specimens of every economic plant would be planted in each garden, and the conditions best suited to any given product could be unerringly discovered. The next step would be to enlarge the gardens by devoting, say, an acre or two in each garden to the exclusive culture of the few products which have been proved to thrive exceptionally well therein. Camphor, for instance, would probably be found to grow well in all the gardens, and it would be a matter of indifference in this case where to extend its cultivation. As its yield and cropping powers are at present unknown, it would be imperative to devote at least an acre to its exclusive cultivation. Kola again would probably thrive best in one of the Wynaad districts, where consequently its cropping powers could be tested.

In a word, there are two principles to be observed,—first to find out where a given plant grows best, and, secondly, to extend its cultivation in order to demonstrate its cropping powers.

The accepted idea of a bureaucratic Government, like the Indian one, is that it should anticipate the needs of its subjects and with a wise forethought lay the foundations of industries previously non-existent. It has done this with tea, coffee and cinchona, but its half-hearted attempts in other directions have met with such slight encouragement that it may be well excused from doing anything further. Ignorance and stubbornness on the part of its subjects, however, should not cause a wise and powerful Government to abandon its efforts. Still, it must be borne in mind that a very slight encouragement on the part of the public would most probably urge it to far greater efforts than if it—the public—maintains its present indifferent attitude.

LETTERS TO THE EDITOR.

WEEDS AND WASH.

Sir,—Your latest *P. O.* to hand, with an article headed "Liberian in the Straits." I should have been inclined to have headed it "Notes on Planting for a Beginner." With reference to weeding, the writer states, "That a good many old and experienced planters argue that it does no harm to have weeds; that on the contrary, in hilly ground, it prevents the top soil from being washed away, and saves the roots of the coffee from being exposed to the sun. Believe me, the planter who argues thus is either a fool himself, or he thinks that you are one," &c. I quite agree with the writer in so far that the man is a fool who believes that the principal reason for leaving weeds is to protect the roots from the sun! But I do think the man who believes that weeds "will absorb all the nourishment instead of the young coffee, and *will also prevent rain from penetrating the soil* and *reaching the roots of the coffee*"!—well to say the least of it, should not think his listeners the fools. Let me refer him to *P. O.*, Vol. II., page 97, and let him read for himself the reasons given by old and experienced planters for leaving weeds, and see if they are what he says they are. For those of your readers who may not have the number referred to by them, or think it too much trouble to refer to it, I may quote the following: * * "The solution of the whole difficulty (the enormous wash caused by the heavy rainfall in most coffee districts) lies in a judicious system of weeding. Some of our most experienced planters,—Mr. G L. Yonge, I think among them,—were of opinion that hand weeding should never be done, but that the weeds should be simply hoed in. After 16 years of experience, I find myself in perfect agreement with the opinion that hand weeding should never be practised. One strong reason against it is that the roots should always be allowed to decay in the soil, as this insures a more equable diffusion of organic matter through the particles of soil." True, that if weeds "be allowed to grow up they will suffocate the young plants altogether," but then who intends that they should be allowed to do so? "*Grass knife* the weeds in heavy wet weather," &c.

It appears to me that your correspondent is of the "Ceylon order of things" and is an advocate of clean weeding on the score of expense. "If an estate is clean, a woman will be able to weed from 200 to 400 trees in a day, but if your estate is under weeds, she will not be able to do more than 10 to 20 trees." They must be really *awful* weeds, them weeds that grow in the Straits! for a woman to do only 10 to 20 trees! For in S. India the task I have given women, and which they regularly perform, in weeds that are as high as the coffee, is from 125 to 150 trees 5′×6′—clean work. However, be this as it may, the clean weeding may cost less, but at what expense? How about the loss of crop, or even of the trees themselves, when the surface soil has been all carried away? Has this not been the cause of the ruin of coffee in Ceylon, together with a want of the knowledge of shade? Is this not the reason for S. Indian planters having nothing to say to Ceylon methods and ways? What has been the ruin of Ceylon Coffee Planting may possibly become the ruin of them also, should they depart from any of their old customs. Coffee is in a more flourishing condition in S. India than it has ever been before, whereas in Ceylon—well, well, draw the curtain! If, then, S. India has left Ceylon so far behind—why will not Ceylon men not take a back seat and modify their views with regard to coffee planting? We should not then hear the so oft-repeated "*that's* not the way we do in Ceylon!" which so exasperates the S. Indian planter, knowing as he does the difference in the condition of the industry in the two countries.

Anti-Ceylon.

GENERAL ARTICLES.

THE SAN JOSE SCALE.

We learn from the *Deutsche Landwrithschafts-zeitung* that the German Minister of Agriculture is taking active measure with regard to the possible infestation of fruit-trees by the San Jose "Schildlaus." A small committee of well-known entomologists and botanists has been appointed to investigate the matter, and steps are being taken to render fruit-growers and other cultivators familiar with the appearances and the life-history of the dread *Aspidiotus pernicissus*. It has been announced that the fruit-growers of Ontario are endeavouring to prevent the importation of fresh fruits and nursery stock from the United States on account of the risk of introducing the destructive scale into the fertile Canadian fruit region between the Lakes. Since we referred to the subject a fortnight ago, the New Jersey experiment station has issued a bulletin, in which it is stated that all hope of exterminating the insect in that Atlantic State must now be abandoned. It is already well established there in gardens and orchards—hedges, small fruits, and tree fruits all being infested. From badly-infested orchards the pest is spreading through the agency of birds. Peaches are especially sensitive to attack, and will die in three or four years from the first appearance of the scale if the latter is allowed to pursue its course unchecked. Thin-leafed varieties of plums appear to come next, then pears, and finally apples. On the other hand, some varieties of cherries seem to be almost exempt. The boundless reproductive powers of the insects and its inconspicuous nature render it especially dangerous, and the opinion is expressed that the San Jose or pernicious scale is the worst and most destructive insect

pest that has ever appeared in New Jersey. Unchecked, it will in time ruin any tree it attacks, and will render the fruit unmarketable long before the tree itself dies.

From Ohio it is reported that, besides gooseberries, currants, raspberries and roses, the San Jose scale attacks the grape vine, the lime tree, the elm, the walnut, the Lombardy poplar, the sweet chestnut, and the guelder rose, all of which grow in England. A favourite victim is the cotoneaster, which is specially liable to attack from various species of scale. In the State of Virginia, where the scale first appeared in 1893, it has not, through lack of systematic treatment, been thoroughly subjugated, and further trouble is anticipated; in Kentucky there is a demand for legislation against the spread of the scale. A fact about which more is becoming known, and which is bound to receive considerable attention in the future development of agricultural entomology, is that insecticides appeal to have different effects in different regions. Thus, it is asserted that insects which succumb readily to kerosine in the Atlantic States defy it absolutely in Colorado. Again, washes that easily destroy the San Jose scale in California are utterly ineffective in the Atlantic States, where this insect appears to be materially altering its habits and life history.

NUTMEGS ON PLANTATIONS.

Among the many valuable trees that would be profitably planted in our plantations, nutmegs occupy a front rank. As a shade tree, *pur et simple* for coffee, it is not suited, but if treated as part of the estate and regularly manured and tended, it should well repay planting. On low country tea-gardens it would be also a useful tree, if planted at intervals in sheltered positions. We take the following account of its cultivation from the *Produce World*:—

The nutmeg-tree being a very remunerative tree to cultivate has naturally attracted the attention of settlers in various parts of the tropical world—East and West; in fact, a nutmeg plantation once established is a permanent source of income, the expenditure on cultivation and harvesting the crop being lower than that which has to be expended in the production of any other class of tropical produce.

The true nutmeg-tree, known botanically as *Myristica fragrans* and *M. officinalis*, easily attains a height of 40 or 50 feet; it is pyramidal in form, evergreen, and handsome in appearance. It is a native of the East Indies, and is cultivated in the Molucca Islands, Java (*literally the Malay word "Java" means "land of nutmegs"*), Sumatra, Straits Settlements, and is especially luxuriant in the Banda Isles, almost the entire surface of three of the group being devoted to it, the volcanic nature of the soil of these islands, the deep shade and excessive humidity of the dense forests being eminently suitable to its growth. It is also cultivated more or less in nearly every West Indian island; some of the finest plantations existing in Grenada.

Cultivation.—In selecting ground for nutmeg cultivation, care should be taken to secure a sheltered spot, protected from the southerly and northerly winds by a skirting of lofty trees, and, if Nature has not already made this provision, no time should be lost in belting the grounds with a double row of some tree of rapid growth; the *Cassuarina littoria* and *Cerbera manghas* are well adapted to this purpose. In the West Indies they plant trees called "Samans" for this shelter. This precautionary measure will not only secure the planter against eventual loss from the falling off of the blossom and young fruit in heavy gales, but will prevent the uprooting of the trees; a contingency to which they are liable from the slender hold their roots have in the soil. If the plantation is extensive, subsidiary rows of these trees may be planted at convenient distances, but no large tree whatever should be suffered to grow in the rows of spice-trees, as such would rob the soil of its fecundity. Virgin forest land is best suited to the crop; but that which is extremely dry or extremely wet should be rejected. Land which is liable to remain under water for any length of time during the rainy season should never be chosen.

The nutmeg requires a mean annual temperature of from 7 78° F., with a rainfall of not less than 65 inches per annum, greater fall would be more suitable; one even as high as 80 inches not being too much. In the West Indies these cli conditions can only be obtained at or near the sea-level, but in climates they are met with at greater altitudes; the trees, how are not so robust.

Seedling trees are almost invariably used for planting. Care sh be taken to select *ripe* nuts; none should be used which do rattle in their shell when shaken. To ensure strong plants largest only should be used. In the East Indies they are usu set direct in the earth, about a foot apart and merely covered lightly with mould. They must be protected from the heat of sun, watered in dry weather every other day, and occasion weeded. They may be expected to appear in from thirty to days, and when four feet high, the healthiest and most luxurian removed at the commencement of the rains to the plantation, viously cleared of trees and underwood by burning and grubbin the roots, and placed in holes dug for their recception at distance of thirty feet from each other, screening them from heat of the sun and the violence of the winds. In the Indies another plan is adopted; the seeds are germinated in bo as many as 500 seeds are set in a "one-dozen brandy case," and the plants are about six inches high they are transplanted bamboo pots, to grow on for another six months before planting they should then be one foot in height, the smaller and the we ones being rejected. It is evident that 1,000 seeds planted in b can be looked after much more conveniently than 1,000 distrib over five acres of land.

In planting the nutmeg from bamboo pots, the first care shoul to prepare a large hole in the ground, some two feet or mor diameter (the larger the better): dig this out eighteen inches or feet deep, put the top spit on one side and the bottom spit als itself. When the hole is complete, turn into it the top spit, m with manure (if available), or if not, the surface soil of the surro ing field or any kind of decomposed vegetable mould, and fill up hole level with the surface mould, treading it fairly solid, sprea the heap of bottom spit earth around the surrounding sur although discarding it for use in planting. In the centre of arrangement a small hole is now scooped out to receive the yo plant. The master must now exercise strict supervision over labourers to see that the bamboo pot is carefully slit down one side, the plant, with the earth undisturbed round its tender root, ge placed in the hole prepared for its reception. If this operation is too clumsily, the tip of the tap root is broken and the plant soon The plants are to be set in rows, as well for the sake of regularit for the convenient traversing of the plough, which is now to be ployed to clear the intermediate spaces of weeds, carefully avoi to trespass on the beds of the young trees. They must be wat every other day in sultry weather until the rootlets are establis and manured annually during the rains wtih four garden baskets of compost to each tree. This compost is a mixture of burnt e and cow-manure in the proportion of two-thirds of the former to third of the latter. When the plants attain the age of five years, until their fifteenth year, the compost should consist of equal par these materials. Manure should *always* be applied *on the sur* If holes were dug to receive it, the roots would be injured, and tree probably die. With *any* land the best system is *mulchin*

pplication of litter and vegetable refuse to the *surface;* this is re's method of affording root protection from drought, also her iable method of applying manure. This tree is always bene- by manure whether situated on forest-land or on the plains. pt in the case of rich alluvial soils, the necessity of applying it rtain intervals has been found indispensable. After the fifteenth the trees require a more stimulating nutriment; the dung ought therefore, to be more than two or three months' old, and the ure should consist of two parts of it to one of burnt earth, apply- welve to sixteen baskets of it to each tree biennially. Some ers prefer to trench in the manure in a circular furrow around ree.

ie nutmeg-tree is naturally *dicœcious, i.e.*, male and female flowers orne by different trees. This fact constitutes a difficulty to lanter, as it prevents him from knowing accurately whether he anting male or female trees. The relative proportion of male female trees produced by the seed is undefined and seems to be esult of chance. The number of male trees necessary to be ned will depend entirely on the number of female trees on hand; above this number being superfluous should be destroyed. s generally considered that one male tree is sufficient to lise twenty female trees. Of course the sex can be ascertained n the young plant flowers, but that is rarely earlier than the fifth , frequently the sixth, and may be much later. Some very erienced growers pretend to be able to determine the sex when young plant is only a foot high, by characters presented in the form and venation, but there is great doubt about the constancy ie leaf formation, and it would not be wise for the young planter ely entirely upon his discrimination in this respect; it is a study ears, and the peculiarities vary with the locality.

s the trees advance in size the lower branches should be gradually ned away, so as to allow access beneath them; but beyond annu- regulating this growth, little or no pruning need be done; and en the trees have arrived at maturiry no pruning is required. At age of twenty years a plantation requires but little attention in way of weeding, as the trees, by the dense shade they themselves rd, prevent the growth of other plants on the ground beneath; previous to this age, weeds need to be well kept down, and until s natural shade is afforded, it is well to occasionally fork the und lightly near to the plant to keep it from baking hard, and s excluding air and moisture. The roots have a constant tendency eek the surface; care should be taken to keep them covered with ild.

Recently it was suggested that a rapid method of obtaining bearing nts would be to graft the two sexual forms upon strong seedlings. eral plants were operated upon (by the process of inarching); as stated, however, that the process was long and expensive, and dly applicable on the larger scale; also, that grafted plants, as a e, are not so long-lived as simple seedlings, and they do not make wth as fast, although they will certainly fruit at an earlier age. may be better for the planter to set two plants close together ead of one in the ultimate position, and then cut out the male ns which may be in excess, or transplant one of the females which y be in duplicate.

For the convenience of planters who wish to economise time in ablishing their gardens, it may be well to note that our Botanic rdens sell young stock plants; thus, at the Royal Botanic Gardens, nidad, young seedling nutmeg plants of one foot in height can be ught at the low price of six cents per plant; the price is about the ne in Jamaica.

Harvest.—Upon an average, the nutmeg-tree fruits at the age of en years, and increases in production till the fifteenth year, when s at its greatest vitality. It is said to continue prolific for seventy eighty years in the Moluccas. Generally, seven months elapse ween the appearance of the blossom and the ripening of the it. The yield is very variable, depending on soil, climate, and culture. The average produce in the fifteenth year of plantation has been estimated at five pounds of nutmegs and a pound and a quarter of mace; but under very favourable conditions trees have been known to yield six times that quantity per tree yearly. It is remarked, however, that some trees produce a greater quantity of fruit whilst others continue to give very little. It bears all the year round, but more plentifully in some months than in others. The great harvest may generally be looked for in the months of September, October, November, and December, and a small one in April, May and June. In some localities, as in Sumatra, it yields abundantly every other year.

All parts of this tree are very aromatic, but only those portions of the fruit called "Nutmeg" and "Mace" are sent into the market. The entire fruit is a species of *drupe*, of an ovoid form, of the size of a peach, and furrowed longitudinally. The nutmeg is the innermost kernel or seed contained in a thin shell, which is surrounded by the mace, and this again is enclosed in a tough fleshy skin, which, when ripe, opens at the tip and separates into two valves. Generally, when nutmegs are fully ripe they fall to the ground, and should be collected once or twice daily. Sometimes they are hooked off the trees with a long stick before they are ripe, but it is best to let them fall. When brought in the mace should be carefully removed, and the nuts placed on the floor of a dry room, or on perforated shelves through which the air freely circulates. They should be turned daily. Freshly gathered nuts should not be placed with those partly dry, but should be kept to themselves until a portion of their moisture has evaporated. To hasten the drying process, the nuts are sometimes deposited on elevated stages placed at a sufficient distance from each other to admit of the heat from a smouldering fire beneath, the perforations in the shelves being sufficiently small to prevent the smallest nuts from passing through. The heat should not exceed 140° F., because a sudden or inordinate degree of heat would dry up the kernels too rapidly, and its continued application produce fissures in them, or fermentation might be excited in them, which would increase their volume so greatly as to fill up the whole cavity of the shell, and so prevent them from rattling when put to this criterion of due preparation. The smoking-house is a brick building with a terraced roof, and the stage is placed at an elevation of ten feet from the ground, having three divisions in it for the produce of different months. The nuts must be turned every second or third day, that they may all partake equally of the heat, and such as have undergone the smoking process for the period of two complete months, and rattle freely in their shell, are to be cracked with wooden mallets; the blow should be struck on the top, not on the side of the nut, to avoid bruising, the worm-eaten and shrivelled kernels thrown out, and the good ones rubbed over simply with recently

prepared well sifted, dry lime. They are now to be sorted into two or three sizes :—

No. 1 should number 60 to 70 nuts to the pound.
„ 2 „ „ 75 to 100 „ „ „
„ 3 „ „ 100 to 150 „ „ „

After this it is usual to again cover the nuts with quick lime—a whitened nut selling much better than one not treated. Finally, they are packed for transportation in tight casks, the insides of which have been smoked, cleaned, and covered with a coating of lime mixed with fresh water. If packed in chests the seams must be caulked to prevent the admission of air or water. A mode frequently practised in preparing nutmegs for the market is to dip the kernels in a mixture of salt water and lime, and to spread them out on mats for four or five days in the shade to dry. Thus prepared they are termed "limed nutmegs," and in some countries they are preferred. The lime is said to preserve the seeds from insects, but injures the flavour. The Chinese wisely prefer to import their nutmegs in the shells, in which they keep good for a great length of time. The shells constitute one-third of the total weight; thus in fifteen parts of the entire produce there are two parts of mace, five of shell, and eight of nutmegs. The process of "liming" was resorted to for the purpose of preventing the germination of the nuts after being shipped to their destination; but it has been proved that this process is perfectly unnecessary, and that simple exposure of the nuts to the action of the sun for a week is sufficient to destroy the vitality of the embryo. Immersion in milk-of-lime destroys many of the nuts; a second process of desiccation is also necessary. (*Journal of the Indian Archipelago*, v.p. 78.) The custom of "liming" nutmegs by the "wet" method is, however, so much in use, and the predilection of the spice so prepared is so strong in certain countries, that nutmegs exported from their native place in the unlimed condition are frequently limed in London to suit the markets of the countries to which they are ultimately destined. As a rule, Penang nutmegs are shipped from that place in their natural condition—unlimed.

The broken, worm-eaten, small nuts may be used for distillation of "oil of nutmeg." The yield of oil varies from 8 to 10 per cent. The *expressed* oil of nutmegs, called "nutmeg paste," is prepared by crushing *fresh* nuts. Broken or imperfect ones are generally used. They are placed in bags and submitted to hydraulic pressure between heated iron plates. The yield is from 20 to 25 per cent. It is at first liquid, but congeals on cooling into an unctuous, orange brown body of marbled or mottled appearance. It is imported into London, principally from Singapore, in oblong cakes of the shape of bricks, but somewhat smaller in size, enveloped in palm-leaves or "flag-leaves." Its odour is very agreeable, and its taste greasy and aromatic.

Mace is picked off the nuts to hand, and prepared for the market by drying it for some days in the sun. At first the mace is crimson or blood-red. It should be dried quickly in the sun, or it is l to mildew and spoil; but it should be kept until it assumes a yellow appearance, as mace showing the scarlet colour, alh perfectly dry, never sells well in the market. During the proce drying, and after a few months, it acquires the golden colour ferred by the dealer. Some growers flatten it by the hands in si layers, others dry it in double blades. In rainy weather arti heat is employed for drying it.

The fleshy outer covering of the nutmeg is used in the Indies for making a most delicious preserve by boiling it with su it develops a flavour peculiar to itself, which is much relishe epicures.

At one time the culture of nutmegs was almost entirely i hands of the Dutch, who took every means to monopolise growth of the plants and confine them to the three Banda mentioned above; but their attempts were partly frustrated pigeon called the "nutmeg-bird," or the "nut-eater," w extracting the nutmeg from its palpy pericarp, digests the mace, voids the nutmeg in its shell, uninjured: this falling in a suit situation, readily germinates. It is related that the Dutch use burn nutmegs when the crops were superabundant, in order to up prices.

LIBERIAN IN THE STRAITS.
III.

Draining, Manuring and First Blossom.

A very important matter in planting is a good system of drain In flat land this will not give much trouble; cut drains east and every five chains and small drains north and south every chain, dividing your plantation into blocks of five chains long by one c wide. In hilly ground, however, the drainage becomes much difficult; and if a planter does not know how to do it, he had b not drain at all. Much less harm can be done by leaving drai alone, than by a scheme which is both bad and wrong. Drain hilly land should be cut on a gradient not steeper than one in every 40 feet; if you cut them steeper, the rush of water wil into the land and wash and carry everything away. These dr should be cut not more than about a chain apart from each o The object of these drains in hilly land is to prevent the soil being washed away by the rain; if that is not done, the roots of trees would soon be exposed and the trees themselves gradu undermined until they also were washed down the hillside. In land we drain to get the water out of our fields, but there is no for this in hilly land, the water quickly enough rushes down the by itself; it is, therefore, more our object to keep the water on soil. If the drains are too steep, the water will pour down wit penetrating into the ground or benefiting the coffee; but if, on other hand, the drains are at an easy gradient, the water will satu the ground and the roots of the coffee will greedily absorb it all the trees will gain health and strength.

Besides this system of regular drainage, I would recommend w holes to be cut between each intermediate four trees, for insta like this:

Apply to

"PLANTING OPINION" OFFICE,
3, ESPLANADE ROW, MADRAS.

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

These holes are about 2 feet square and are intended to catch the n water and to keep it until it has gradually been absorbed by the ound and surrounding trees. The holes will in course of time fill and then you can cut new ones between the intermediate four es which had been left undisturbed before. I have found this to as good if not better than any manure; anyhow, it is very ap and very effective.

But I don't mean to say by this that you should not apply manure sides having these water holes. If you depended on drains and ter holes alone to give sufficient nourishment to the trees to pro-ce a good crop and regular returns, you would soon find out that vas a fatal mistake. For several years the coffee tree has absorbed e nourishment out of the ground and this must be replaced.

We read in the Bible of the widow's cruse of oil which never led, and we naturally marvel at such a miracle; yet there are a mber of planters who expect their ground to perform the same nders, and are surprised when their coffee trees after a lapse of ars begin to show signs of decay and weakness, although they ve never thought of returning to the ground what their trees have ken out of it.

Your ground should be manured regularly every year, and the rlier you begin with it, the better it will be for the coffee.

There are very many ways of manuring, and I dare say they are l good; but, as I said before, you must know what you are about. have seen planters manure with bone meal and oil cake, and all nds of different artificial manure. I have seen the trees being rced to produce a crop of 8 to 10 pikuls and more an acre in one ar—and never again afterwards!

Mr. T. H. Hill, the pioneer planter of the Malay Peninsula and a cognised authority on coffee cultivation, writes (*Straits Times*, th June, 1893):

"Whilst there are many planters who disbelieve in what they are eased to call artificial manures, I would call their attention to the periments at Rothamstead, by which it has been proved to be acticable to grow the same crop on the same land for 30 or 40 ars in succession with artificial manures alone, and in instances e results, not a few, have equalled that of land yearly manured ith cake-fed farmyard manure at the rate of 14 tons per acre per nnum for the same term of years. These papers are open to the nsideration of all by the great liberality of Sir John Dawes and r. J. H. Gilbert. In comparing these examples with perennial ltivation like coffee, the value is very great, owing to the same op having been and continuing to be grown on the same land for a ng term of years. On the other hand, we find further corrobora-on starting later on, so far as I have been able to learn, only pub-shed in a more summarised form in the book published by M. eorge Ville, entitled 'Artificial Manure.' After looking carefully ver the formulas for manuring employed on Rothamstead, it is ost reassuring to find that the nearer the manures employed pproach to those advocated by M. George Ville, notwithstanding ne variety of the crops generally, the results are the most favour-ble; thus, by an independent source, proving the enormous value of ne work that has been done at Rothamstead to the whole agricul-ural community of the world. You will observe from the foregoing hat I am of opinion that high cultivation is necessary to produce arge crops and that the soil in itself is not rich enough to bear a uccession of large crops; this is so, and whilst nature has most chly endowed the Malay Peninsula with an extremely fertile climate, he soils, neither by analysis nor results without cultivation, are ound sufficiently rich to produce a succession of heavy crops with-ut skilled manuring and careful cultivation. When it is brought o notice that for each pikul of clean coffee it has taken nine pikuls f fruit to produce it, the desirability of high cultivation becomes at nce apparent. On looking back over a series of years of the crop eturns from different fields, it becomes plain that, for many years, have been removing a gross weight of from 4 to 5 tons per acre."

Too little and too much manure are both equally detrimental to he growth and development of the coffee tree. The tree must not e starved, but neither should it be forced to produce more crop than t can reasonably be expected to bear and to stand. The object of nanuring is to strengthen the tree by returning to the soil what has een taken from it, so that the tree will always get the nourishment which a strong plant requires to keep it healthy and vigorous. To chieve this object I would recommend:

(1) To changkol (hoe) the ground all round between the trees, but not nearer to the stem than the branches extend above the ground; generally the roots have spread under the ground just as far as the branches above and the object of changkoling the earth is to let the soil evaporate, to allow the superfluous gas to escape and to give the roots a fair chance to spread further out, and as a consequence the branches will follow too and gradually cover the whole ground from tree to tree. This being once achieved you have gone ahead a good deal more than you may probably be aware of, or than many experienced planters will admit. The roots of the coffee want shade and the tree will greatly benefit through this; the weeds, again, want light and sun to keep alive, and thus whilst benefiting the coffee, you deal at the same time the death-blow to the weeds, the mortal enemies of coffee.

(2) It takes, of course, several years before the branches of the coffee tree have developed so far as to cover the whole ground, and in the meantime I would advise covering the ground with lalang. This is very effective; I have used it myself with great success in old coffee which was at the point of starvation, and the coffee has recovered wonderfully. Lalang being spread on hilly ground prevents also the washing away of the soil. Many planters are afraid of the great risk of fire, as dry lalang, as everybody knows, will burn like straw if a match is put to it; but this danger only exists during the first few weeks, then the lalang having been exposed to rain, wind and night dew, has become so moist and rotten that it will be found quite impossible to burn it. As a fair day's task a cooly will cut 30 to 40 bundles of lalang of about 2 feet diameter.

(3) The application of manure is done in many different ways. Some planters cut a semicircle above the tree, about 3 or 4 feet away from the stem so as not to disturb the roots; others apply the manure in a hole cut between each four trees; others, again, supply it in the same manner as the water holes I have described above.

I make my coolies cut holes in a semi-circle round each tree as far away from the stem as the branches extend, but never nearer than 3 feet. These holes should not be less than 3 feet long and not less than 1 foot broad and 1 foot deep.

I mention this specially, because many planters are afraid to cut more than half a foot deep for fear of injuring the roots of the coffee. This, however is quite a mistake: you should work the ground up as deep as possible, certainly not less than one or two feet. If the ground thus worked up is thoroughly mixed with the manure, the desired effect on the coffee will have been effected, but not otherwise. It is astonishing to see how hard the ground is when you begin cutting holes as described above, and it will at once be evident to you that this ground will not allow the roots to spread, and that it is indispensably necessary to dig it up at least one or two feet.

Another part of my system of manuring is that I do not apply the manure to the trees at once; my coolies have to cut the holes first, and these holes remain open until after a few days of rain; it will do the coffee all the good in the world if these holes are filled with rain water—anyhow, you may be quite sure you cannot do the least harm to your coffee by letting them remain open for a few days. This system will enable you to examine every hole and to see whether it is of sufficient size; besides it has the effect of thoroughly working the whole of your ground over, admitting fresh air and allowing bad gas which has accumulated to escape, and, another important factor, it disturbs the nests of dangerous insects, who have been accustomed to consider your ground as their undisputed property and home, whence they could unmolested attack and destroy the coffee trees and their crop.

The best manure for coffee, in my opinion, is cattle manure. A good basketful applied to each tree and well mixed with the soil will be about the right quantity. A cartload is 30 to 40 basketsful and costs about 30 to 50 cents delivered on the estate. The manure should be applied shortly before the rainy season (on old estates, at least two months before the crop ripens, otherwise the crop will not get the benefit of the manure and the tree being weakened through the disturbance of its roots just at a moment when all its strength is required to ripen the crop will rather suffer than benefit through the application of the manure).

If all the above has been carefully observed, you have only to wait patiently, and after one or two days of a good and continuous shower of rain—a rain which everybody else calls a beastly and most annoying sort of rain—you will see something which will make your heart rejoice. The ground having been thoroughly saturated by the rain, you find on getting up, one fine morning, the whole of your plantation

one sea of snow-white blossoms—a sight worth seeing, but to a planter the realisation of three years' hard work, unceasing worry and care, endless troubles and difficulties. He then experiences a feeling of happiness and satisfaction and a heavy load is taken off his mind. There, at last, is the reward for his perseverance, his patience, his energy, his pluck, his time and care.

It is not necessary to be a planter to imagine the pleasure of such a moment. Here is a man who has staked all he possessed in a coffee plantation, he has cut and cleared the jungle, sown the seed, planted trees, laid out every road, traced every drain, built every house, and, what is more than the money he has risked, he has actually spent three or four years of his short life, a treasure which no money in the world can bring back to him—every tree on the estate is a part of his own life, and there he sees for the first time the dream of his ambition realised. Well, but there is many a slip 'twixt the cup and the lip, and I believe it was Solon who said that no man could be counted happy before his death; and so, I should say, no planter can depend upon his crop before he had actually harvested it and sold it and placed the proceeds to his credit at the Bank.

But don't let me conclude this chapter with gloomy anticipations and probable possibilities, but, on the contrary, let us hope that there will be a good crop. A fine blossom is a fine sight: it gives new hope to the planter, and it is this hope, the expectation of the nice and good things which we always hope may yet be in store for us, which keeps us going, makes us undergo endless hardships and deprivations in our life, and which, after all, so very seldom are realised.

(*To be continued.*)

GOOD FOOD—GOOD DIGESTION—GOOD CHEER.

"Moral character is located in the stomach," says a recent writer. He is wrong; but there is a shade of truth in the idea he throws out. Napoleon was often willing to trust others to look after the arms and ammunition of his armies, but the commissary department he looked after himself. The bravest men won't fight unless they are fed, he said. Nor will they.

That's why we are not surprised to find Mr. William Jones saying that at a certain time he was in a low and desponding state of mind. He gives the reason himself in three words, "I was weak." And why was he weak? He explains that, too.

"I was always strong and healthy," he says, "up to January, 1892. Then I had a severe attack of influenza, followed by congestion of the lungs. After this I never got up my strength, and I was low, weak, and desponding. I had a bad taste in the mouth, my appetite was poor, and every morsel of food I took gave me intense pain at my chest. After every meal I was sick, vomiting a green filthy fluid, which was often mixed with blood."

We shall have no trouble to understand this especial phase of Mr. Jones' illness. The green, filthy fluid was mucus mingled with bile, and the blood came from some of the small blood-vessels, which were ruptured in retching and straining. The bile was out of its place; that's why nature tried to get rid of it. But how did it get out of its place? Wait a bit; we'll come to that presently.

"I had," continues our friend, "dreadful attacks of cramp in the stomach, and the gnawing pain was well nigh unbearable. At night I got but little rest; sometimes none at all—cold, clammy sweats breaking out all over me, and in the morning I had barely the strength to raise myself. When I went out of doors my breathing was so bad I had to step and rest every few yards.

[The cramp was caused by the gas arising from the fermented food, and the short breathing by a partial paralysis of the nerves, created by the poisonous acids which had entered the blood from the stomach. The nerves were also enfeebled by the enforced starvation—like all the rest of his body.]

"As month after month went by," says Mr. Jones, "my relatives and friends could see me wasting away and apparently sinking into the grave. I became as *thin as a lath*, and you could see through my hands. My legs and face were attenuated to the same extent, and as for my muscles they seemed to be all completely gone."

[Now, inasmuch as when people waste away the fat goes first, and the muscles and other tissues last, you can perceive how far advanced in a decline our good friend really was.]

"Yet I continued in this condition," he says, "altogether for seventeen months. I was attended, off and on, by four doctors, their medicines had no good effect on me. I also used lung to and cod-liver oil, but to no purpose.

"In June of this year (1893) I first read of Mother Seigel's Sy and my wife got me a bottle from Mr. Cole, the grocer, at Grosm After taking it a few days I was relieved, my appetite improved, the sickness (the nausea) left me. Keeping on with the S I gained strength every day, and in a month I could walk and and was soon as well and strong as ever. Your remedy saved life, and I wish others to know it. You can refer enquirers to (Signed) William Jones, Bridge Inn, Kentchurch, Pontrilas, H fordshire, October 31st, 1893."

The case of Mr. Jones and his recovery as set forth by him well known in his neighbourhood. His wife says that one of doctors told her that all hope was gone. But happily the do was mistaken, as the wisest of us sometimes are. His disease chronic inflammatory dyspepsia, and that only. But that enough, mercy knows, and a fatal end to it was not far off w Mother Seigel's Curative Sprup had a chance to do its hea work.

Our friend is cheerful now because he is strong; and he is st because this remedy set his digestion to rights.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (March 11, 1898) say Public sales have been on a small scale this week, but in spite of thi demand proved slow except for desirable parcels which were easily posed of.

Barely 900 bags East India were offered, chiefly Coorg, the finer gr of which realised very full prices whilst the remainder sold steadily.

The light supplies of Central American catalogued met poor compet at rather under previous rates, whilst a good proportion had to be bo in.

A weak tendency has prevailed in the Terme market this week o to a further increase in the Brazilian receipts, and quotations sh decline on the week of 1/- to 1/3.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Market the Week ending March 9th, 1898, says:—Bank rate 3%. Bor Exchange closes at 1s. 4d. Brazil Exchange 6⅜d. Rupee p 3½% 63½. Silver 25⅛d. per oz.

This market has ruled flat throughout the week, and importers h anxious to sell, all kinds are lower, except East India, of which the su was small: London cleaned Salvador and Guatemala show a declin fully 3s to 5s; Costa Rica is about 1s lower except fine.

Daily receipts averaged 10,600 bags in Rio, and 11,300 bags in Sant

Futures have been flat, and at the close show a decline of 1s to 1 per cwt., viz.:—Good average Santos in Havre, May delivery, fcs. 3 in Hamburg pf. 29¾, and No. 7 low ordinary Rio in New York $5.40.

To-day's London official quotations are:—

	March	May	July	Sept.	Dec.,
Santos ...	28/9	29/3	29/6	30/-	30/6

TEA.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, dated March 11th, 1898, says :—

QUANTITY BROUGHT TO AUCTION IN LONDON

FROM 1ST JUNE TO DATE.

	Indian.	Ceylon.	Java.
1897-1898...	1,328,871 packages.	928,422 packages.	32,611 packages.
1896-1897...	1,369,718 „	878,769 „	32,180 „

32,393 *pkgs.* INDIAN
19,476 „ CEYLON
2,122 „ JAVA
} Total 53,991 packages were offered in public auction this week.

Countries outside the United Kingdom took nearly 9,000,000 lbs. more Indian and Ceylon Tea last year than in 1896. Progress in these external markets has been not only steady but rapid, viz. :

	1897.	1896.	1895.	1894.	1893.	1892.
Indian..	22,198,810	19,206,172	16,815,323	14,149,904	14,027,129	10,029,328
Ceylon..	28,949,314	23,465,733	19,923,803	14,563,082	13,138,544	9,583,285
Total lbs.	51,148,124	42,671,905	36,739,126	28,712,986	27,165,673	19,612,613

In spite of the relief afforded the London market by an external demand for 51,000,000 lbs. in a year, prices are unusually low. Where would they have fallen but for this relief? Though present quotations will doubtless lead to further development, no effort must be relaxed if these markets are to become permanent users of our Tea.

Export of Indian and Ceylon Tea in lbs. to places outside the United Kingdom from 1st Jan. to 31st Dec.

INDIAN.

	1897.	1896.	1895.	1894.
Re-exports from U. K. ...	5,496,539	4,399,640	3,973,531	3,551,282

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, ght Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including stage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for e advertisements will be: 4 as. per line for the first, 3 as. for the second, d 2 as. for the third and succeeding insertions. Five-line advertisements m Subscribers will be inserted for three issues for one rupee; non-Subibers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic currence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," planade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been moved to Madras, all remittances should be made payble to the Manager of *Planting Opinion*, 11 and 12, econd Line Beach, Madras, who will also attend to all dvertisements, &c.

Letters to the Editor should be addressed to Coonoor, s usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 15th April, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nellampatty (British).

6th April.—Weather.—No rain yet; several times it has seemed as if rain would fall in a few minutes, but it has held off, and now there are very few clouds about at all. Thunder has been frequent, sometimes fairly near too. *Crops.*—Spike holding out wonderfully, but it can't do so much longer. *General Health.*—Fair: fever prevalent.

Coorg.

POLLI BETTA, 31*st March.*—Good rain out Siddapur way beyond the Club on Tuesday. Also out east. Central parts got little or nothing. Cleared up yesterday again. No more rain can be looked for till next Sunday, Monday and Tuesday. *Crops.*—Spike still holding out. There has been very little burning. *Public Health.*—But little improvement. *Interesting Items.*—Volunteer Camp at Mercara and Inspection on 29th. Dinners, balls, races and general hilarity till 2nd proximo.

Nilgiris.

KOTAGIRI, 6*th April.*—No rain in March, except 0·09 in. on the 4th; rainfall to end of first quarter 7·12 in. against average due 7·19 in. Spike of main blossom is forward, for which early rain is wanted. Moisture is also needed on first show on places that had heavy rain and a good blossom out in February. Generally speaking, most estates can wait comfortably for some little time yet, and some will be all the better for deferred wet weather. It worked up for rain at the close of March for many days every afternoon, but the high east wind now prevailing has dispelled all signs of early moisture to come. Promise is very good if rain does not fail.

KULLAKAMBY, 7*th April.—Weather.*—No signs of rain, and the heat increasing. It is hoped the full moon may usher in a

change of weather, or prospects will look gloomy. *Crops.*—Badly in want of rain. Spike holding out fairly well, but a continuance of this heat and dry weather will prove too much for it, especially where shade is insufficient. *General Health.*—Fever and influenza still going about. *Labour.*—Sufficient for the work in hand. *Interesting Items.*—Jungle or scrub-fires very frequent; some parts of the district have been burnt so thoroughly that there is not a blade of grass or green scrub visible for miles.

Coonoor.—*7th April.*—It is working up again gradually for rain, though the wind has been very high this last week. Except on the very lowest estates, coffee is standing the drought very well; spike is being well developed, and timely rain will bring out and set a first-rate blossom. Tea is not flushing extra well. It wants rain very badly indeed. Health at present indifferent. Badaga labour scarce owing to their sowing their fields with their everlasting sámi (millet). Nominally this grain is ridiculously cheap, but owing to the increase in Badaga population, it is most difficult to buy it in the open market.

Nellakotta.—*6th April.*—*Weather.*—From 25th March to 2nd instant rain came up every afternoon to N. and N. W., but none fell here, though heavy showers fell at Sultan's Battery, about 6 inches distant in a bee line. This probably means another fortnight without rain. Over our feelings, and the way we express them, I had better draw a veil. Blazing hot weather at present. *Crops.*—Crop here is on the knees of the gods. Spike is holding out well, but it must necessarily suffer to some extent from this continued drought. Oh the pity of it! for there is a splendid show of spike all over the district. *General Health.*—Every one is out of sorts from this continued suspense and the trying weather. A shower of rain would do us, physically, as much good as it would do the coffee. Some fever amongst coolies. *Labour.*—Sufficient for hot weather work.

NOTES.

Keeping seed. Romanes showed that seeds could be kept a year or more in a vacuum without detriment to them, and it has also been found that when sealed in vacuum tubes they do not exhale nitrogen or carbonic acid. Professor Dewar and Mr. Horace Brown have demonstrated that seeds can be submitted to a temperature as low as that of liquid air (180° below zero Centigrade) for 100 hours without impairing their power of germination.

Leaf-disease in Travancore. A South Travancore correspondent brings to notice the fact that, despite "Nitric Acid's" contentions, leaf-disease attacks coffee in different ways according to the particular district affected. "I agree with him," writes our correspondent, "about nitrates being a great help during leaf-disease, but his premonitory symptoms are, down here, conspicuous by their absence. Here it takes coffee apparently in its prime."

Measuring an acre. Though most of our readers find it perfectly easy to measure an acre of land by the simple way of figuring out the square root of the total number of square yards it contains, *i.e.*, 4,840, the following notes may be useful for ready reference:—Five yards wide by 968 yards long contains one acre; 10 yards wide by 484 yards long contains one acre; 40 yards wide by 121 yards long contains one acre; 70 yards wide by 69½ yards long contains one acre; 80 yards wide by 60½ yards long contains one acre; 60 feet wide by 726 feet long contains one acre; 110 feet wide by 397 feet long contains one acre; 130 feet wide by 363 feet long contains one acre; 220 feet wide by 181½ feet long contains one acre; 440 feet wide by 99 feet long contains one acre.

South Indian Teas. Messrs. Arbuthnot & Co's Monthly Market Report, dated London, 11th March, says:—

About 1,500 pkgs. were included in the catalogues, bringing 6½*d.* p. lb. opposed to 6¾*d.* p. lb. for 5,648 pkgs. in January last. Quality on the whole was not very attractive, and as the supply of ordinary kinds from other producing countries is rather plentiful, prices for the most part were easier. Among the Travancores, Kudawa Karnum, Atchencoil, Wallardie, Venture, Stagbrook and Carady Goody sent useful shipments, and there was an invoice from Pykara Falls, Neilgherries, possessing fair flavour, also from Perindotty, S. Wynaad, but the others generally call for no special notice.

Our readers will probably recollect the very poor prices obtained until lately by the Perindottty (Wynaad) estate. The improvement noted is, therefore, all the more gratifying as showing what improved management can effect.

Shadeless shade-trees. With reference to "Evergreen's" query *re* the deciduousness of *E. lithosperma*, we insert the following remarks from the usually well-informed Coorg correspondent of the *Planter*. Of course the use of shade trees varies according to district and elevation:—"A stranger visiting coffee estates at this time of year would be struck with the number of leafless shade trees that are to be seen in them, and would, I fancy, be surprised that trees of this descriptiou should be retained as shade trees when they become devoid of leaf at about the hottest time of the year. But the primary object of shade is to keep down borer, and so what has got to be looked to is that such trees should be provided as will be in full leaf during the borer incubation periods, which is, I believe, about November, December and May. It is for this reason that trees which lose their leaves at the beginning of what is called the cold weather are of no utility in checking borer. The trees which are now leafless will all be in leaf again before May, and are, therefore, some of the most desirable kinds of shade trees. Not a very high temperature is required for the hatching of borer eggs, as they have been found to hatch out in the shade of a verandah of a bungalow."

The Odessa market. For some unexplained reason, or perhaps for no good reason at all, writes the *Pioneer*, mercantile enterprise in India has greatly neglected the very promising market for Indian produce which seems to exist at Odessa. Such goods as tea, coffee, and jute are quick to make their way in new markets if properly pushed, but though the more alert merchants of Ceylon export large quantities of tea to the Black Sea, Indian tea exporters have so far left this market unexploited. Freights for Indian produce by the Volunteer Fleet steamers which run to Odessa from the Far East rule very low, and the shipowners, we are told, are keen to do more business. Volunteer Fleet steamers call at Colombo regu-

larly and at ordinary times—that is to say when there is no plague in India to raise quarantine difficulties—at Cocanada also. It certainly seems a pity to see steamers which are capable of carrying thousands of tons of Indian goods to Russia sail to Odessa with perhaps only a few hundred tons of tea or coffee from Ceylon, and a little castor-oil seed from Cocanada. There is a large jute factory at Odessa, and most of its jute is supplied from India, though a small quantity of the best sorts is sent from Resht in Persia. In this direction, as in many others, there appears to be an opening for Indian merchants. Mr. J. H. Frontmann is the largest dealer at Odessa in Ceylon and Indian teas, and a British subject, and he may be addressed by anyone in India desiring to make further enquiries.

China's struggles. Messrs. Davidson & Co., the well-known tea machinery manufacturers, are at present, we learn from a Ceylon contemporary, very busy supplying tea machinery to various parts of the world. For instance, we hear that they are about to supply three large rollers and other machinery to the order of a Russo-Chinese Syndicate, which is about to establish an immense factory in the heart of China, some distance up the Yangtse river. This machinery will all be erected by Messrs. Davidson & Co's assistants, and it is probable, we understand, that Mr. MaGuire may himself be sent to supervise the work, as he has been called upon to hold himself in readiness to leave for China or any other part of the world at a few days' notice.

Messrs. Davidson & Co. have also received a large order from the Russian firm of Popoff Bros., to supply about £6,000 worth of machinery and material for the equipment of a factory on their experimental tea estate in the Caucasus. There are three estates there—one belonging to the Russian Government, another to a Moscow firm, and the third to Messrs. Popoff Bros. This last consists of 250 acres, and Messrs. Davidson & Co. have been ordered to fully equip a first-class factory for it. They are therefore despatching from Belfast rollers, witherers, and driers, as well as sifters and cutters; so that the experiment of growing tea within the Russian dominions is not to be hampered through lack of adequate machinery. In all probability the work of erection will be carried out under the personal superintendence of Mr. Harry Davidson, who was recently in Ceylon.

Quick method of tree propagation. Though well-known perhaps to some of our readers under the name of "Gootee" propagation, the following description will be read with interest by those unacquainted with the process :—

"There are many people who have in their garden a favourite standard fruit-tree of some kind,—be it apple, plum, pear or any other fruit,—which they are inclined to think is a much better variety of that particular fruit than anything else they have seen. Now if they bud a stock from this tree, it will be some years before they get any result ; while if cuttings are taken, this is a method required still longer. It very often happens that on these trees there are some boughs which hang down a bit and which get in the way sometimes, and if such a bough does exist, which the owner thinks could be spared from the tree, and it happens to be of a decent shape, there is no reason why it should not be turned into a tree on its own account, to do which it is only necessary to follow this simple plan. First decide on your bough, and then on what height (according to its length) you would like your tree to be, and then, in the spring, at the spot you think suitable, take off a ring of bark about three inches or four inches wide ; a small quantity of good soil should then be put in position round the part from which the bark has been taken, by tying round it a piece of matting or sacking in such a manner that it cannot drop out. This should be kept moist during the summer (an oil-can filled and hung up close by, and connected with the matting or other material by a piece of soft string or wool, will do this with very little trouble), and roots will soon form in the soil which has been placed there. In the autumn the bough may be cut off just below the spot which has been so treated, pruned into shape, and planted, and in the following season it will bear fruit."

Erythroxylon coca. I read with interest, writes a correspondent to a Calcutta exchange, your article on the revival of attention to the cultivation of *erythroxylon coca* which is known to grow on these hills. Several bushes existed in the Burliar garden, a subtropical Government Garden maintained for the growth and acclimatisation of the fruits of the archipelago and the vegetable products of the plains. It lies at an elevation of 2,500 feet above sea level, and possesses a rich forest soil [*Possessed ;* the soil is now principally hard sub-soil, and almost impossible to dig.—Ed.] but a deadly malarial climate. It is certain that coca will thrive in many parts of Southern India, and may be easily propagated from seed, but it is doubted whether it will be probable for the European planter to grow it on a large scale. Vast tracts in South America are cultivated wtth the plant for the purpose of manufacturing the valuable alkaloid *cocaine,* but the market price of the alkaloid fluctuates so largely that planters have no confidence in the price. One time *cocaine* fetches 2*s.* 6*d.* grain, another it falls to 7*d.* and lower. Writers on economic products are cautious in their advice to grow coca commercially, and wish the popular reports as to the profitableness of the trade to be freely discounted. Some years ago the Government Genealogist analysed samples of leaves of coca grown at Burliar, and succeeded in obtaining the alkaloid in a crystalline form. It was used by a Madras ophthalmic surgeon with complete success in some of his operations. Another doctor suggested that *cocaine* should be added to the ingredients used in the manufacture of cough lozenges, because he found that the chewing of the leaves gave relief in cases of spasmodic bronchial coughs. The experiment above referred to showed that ½ per cent. of the alkaloid could be extracted from the leaves grown at Burliar.

A bug fungus. Amongst the enemies of the coccus, says the *Madras Times,* is one discovered lately in the Southern Continent, and another parasitic fungus, of an almost identical order, which obtains and is largely employed in America, known scientifically as Microcera Coccophila, and vulgarly as "redbug pest or scale tubercle." We trust Mr. H. O. Newport will have his attention directed to the Australian bug fungus,

which might well prove as useful as the redoubtable lady-bird itself. The description of this in the dictionary is interesting. Briefly speaking, it has earned its name because of its forming a minute, deep, brick-red tubercle upon the scale. The fungus destroys the scale by riddling it with its vegetable system, producing its death. The scales eventually fall off, and leave the surface of the tree clean. Like all plagues, this natural prey on the scale is communicated with great rapidity throughout an infested district, once it gets a foothold. The sporous bodies are detached and carried by the breeze or other agents from tree to tree. In the United States artificial cultures of the fungus are produced in large quantities, and sent by the State departments to any infected districts. When the scale, the natural prey of the fungus parasite, is exhausted, the fungus dies from lack of nutriment. The *Argus* states that Mr. M'Alpine first discovered the fungus in 1896, having found it rather plentifully on some orange leaves sent from the Sydney Botanic gardens, parasitic upon the red scale of orange. In several parts of India scale of more than one sort is only too well-known, and it would be well could Government procure some of the fungus for purposes of experiment and research. It may be that our own Agricultural Department, when there is a little rest from writing reports, may discover a bug pest made in India.

Wine from leaves. A French druggist has conceived the idea that the flavour of the fruits of shrubs and trees is generated in the flowers of these plants and passes from them into the fruits. The fragrance which the leaves of the black currant bush give off, especially after a little rubbing, and which is so very similar to the taste of the berry, has led the man to adopt this opinion. He goes further and says that the pleasant taste of the apple, pear, or grape is prepared in the leaves of the respective plants, although he admits that it is hardly noticeable with these and by far not in the same degree as with the black currant. But this does not discourage the inventor. He sees glycoside, which he proposes to decompose in sugar or a more or less aromatic principle, as he sets forth in the Union Pharmaceutique. The respective leaves are to be crushed and a fermenting agent, such as yeast, is added to them, whereupon the odourless and tasteless glycoside decomposes and the chemical principle becomes free, which is to impart to the fruit proper its aroma and pleasant taste. What was formerly sought to be accomplished with apples, pears, grapes, &c., is now done in a simpler manner with the leaves in the fomenting vat. Jacquemin, for this is the name of the inventor, places these plants, *e.g.*, apple tree leaves in water containing 15 per cent. of sugar; then he adds the yeast. During the process of fermentation there is an odour of apples, and when the fermentation is finished and the yeast has settled, a straw yellow liquid is obtained, which possesses the fine "bouquet" of the fruit of the respective trees from which the leaves were taken. With vine leaves the results are still more prolific. A beverage tasting and smelling strongly of wine is obtained, and finally brandy may be distilled from it, which is similar to the best cognac !

Terracing vs. Draining. It may throw some light on this subject that has been lately so energetically discussed in these columns if we extract the opinions thereon found in the Tea Cyclopædia of 1881. A Sylhet planter tested what he calls "flat or round" terracing, the terraces each being three feet wide, against ordinary unterraced cultivation of the same shape. The tea on both fields were planted at the same time, and were otherwise treated in exactly the same way, save that the terrace edges were left unhoed. From the first the plants on the unterraced field grew a great deal better and stronger than on the terraced field. Another and older field which was terraced gave a good yield previous to that treatment, but deteriorated as soon as the terraces were made. The explanation given is that the terrace walls, by cultivation being prevented at the edges of the terraces, grew hard and compact and hindered the free growth of the tea roots. The same writer says he has observed precisely the same results on many other gardens. Another Sylhet planter especially condemns what he calls the honeycomb pattern of terrace, which act simply as receptacles for water. He describes them as follows :—"In this sort a long pit is dug between the lines, the pit extending across the slope; these pits are suffered to stop the wash or rush of water down the hill and to save loss of soil. The plants thus rest on a bund as it were, and their roots, especially in poor soil, are confined to that bund. In the hot sunny weather the roots suffer from drought. If cultivation is attempted, the pits or trenches are filled up. In rainy weather water lodges in these pits and the plants suffer from excessive moisture. With the "round" terrace weeding is a matter of great difficulty and expense. A good hoeing three times a year, without any terracing, will largely stop wash and be a great deal more beneficial to the plant.

We may mention, by the way, that the *Indian Planters' Gazette*, in noticing the correspondence, has asked its Darjeeling readers to throw more light on the subject.

The "honeycomb" terracing of Sylhet is, of course, what is known in South India as "continuous trenching," a method of cultivation that to our mind has little to recommend it. The old straight digging fork, if used to merely loosen the earth, and not to invert the clods, takes the palm, we venture to think, for really efficient cultivation in theory as in practice.

To make a soil healthy. Last year we published a series of interesting articles on the relation of the soil with leaf-disease, but we fear a certain proportion of our readers found the style too scientific for their taste. The following notes on the same subject are an abstract from a letter by the same author, and will, we hope, be found easier of comprehension.

If on a rich soil, either old or new, coffee or tea does not come on as as well as it should, the most likely explanation of the failure will, in our South Indian soils, be that the soil is deficient in aeration. This may be tested by having the soil fully analysed, especial attention being paid to the ferrous oxides present; also the carbonic acid and organic matter, while the nitrates present should be shown separately from the total nitrogen. Ferrous oxide is a low and dangerous form of iron, which possesses an extraordinary power of attracting to itself the free and combined oxygen in the soil. A large proportion of this undesirable mineral will, therefore, show that the soil is very badly off for oxygen.

Without oxygen nitrates cannot be formed, and until the demands of the ferrous oxide are satisfied by means of very thorough aeration, the plant growth of coffee and tea will not succeed. When an analysis shows that ferrous oxides are abundant, nitrates deficient, though nitrogenous humus may be present to excess, and carbonic acid is only in small quantities, the conclusion is inevitable that the soil is not sufficiently aerated.

The first thing, therefore, that such a soil requires is perfect drainage to draw off the excessive moisture held by the large quantities of humus present. For until this moisture is drawn off, air cannot enter the soil. Perfect drainage is essential, even to the extent of running drains between every row of trees. Oxidation must further be forced on by means of lime carbonate. Nitrates of various forms being so generally used nowadays, it is advisable to consider the best time to apply the lime in relation to the nitrates. It would be advisable to apply the lime several months, or even a year in advance of the nitrogenous manure, to enable the soil to convert the latter into nitric acid, or to hold up the ready-formed nitrates without danger of interference from the ferrous oxides. Nitrates and lime must not be applied together, otherwise a loss of nitrogen ensues. Or if this is unavoidable, several inches of soil must separate the one from the other.

The London Market.

Coffee.—On the 1st instant the summary of the stocks, says the *Produce Market Review* of 12th March, shows that there has been an increase during February of about 8,000 tons in the European stocks, but a decrease in the world's visible supply of 760 tons. The latter is doubtless due to a falling off in the receipts at Rio and Santos during the month, but this week there has been a very considerable increase again, and the total, though there are still four months of the crop year to come, is already in excess of the amount received during the whole of the previous year, which was the largest on record. This, but more particularly a further rapid fall in the Brazilian exchange to 6¼*d.*, has had a weakening effect upon the market, particularly on the terminal market which has fallen from 9*d.* to 1*s.* 6*d.* below the previous very low quotation. At auction the amount offered has been smaller than usual, particularly with good home trade kinds, and as the export demand keeps slow, rates have, in many cases, given way; Colombian and other Central American sorts from 1*s.* 6*d.* to 2*s.* per cwt., and Costa Rica, excepting the few lots of fine coloury parcels, about 1*s.* per cwt. Only small lots of East India and Plantation Ceylon have been offered, and these have sold well at full prices.

Indian Teas.—The supply has been moderate, but as there is no material improvement in the demand, the change in values is not important. The proportion of the offerings of very common teas was again large, and lower quotations were in some cases established. As these grades have to compete with the lower qualities of Ceylon now being freely brought forward, and as the latter are better in appearance, it is not surprising that their value should fall. On the other hand, similar descriptions, giving a better result in cup, were steadily competed for and fetched prices equal to those of last week, and as the supply is not likely to be too plentiful, present rates may probably be well maintained. The finest teas continue to be actively competed for, the quantity offering being unusually small, and prices in consequence show a decidedly firmer tendency. It would appear that the highest point has not been reached, although it is quite probable that any further important advance would check the consumption of the finer tea. The medium sorts, although not meeting with such a good inquiry as a few weeks ago, have not changed in value, excepting those giving a poor infusion but with fair appearance, which sold in buyer's favour. Of the 31,613 packages submitted to public sale 6,290 were withdrawn, being a larger proportion than usual. Most of the catalogues contained final invoices from the different districts, and many of these teas are as poor in quality as at any period during the season.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton:—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

Advertisers are notified to send all advertisement matter and answers to advertisements direct to Manager, this paper, 11 and 12, Second Line Beach, Madras.

Correspondence and matter for publication to be sent to Editor, this paper, Coonoor.

LETTERS TO THE EDITOR.

ASH TIMBER SUBSTITUTES.

Sir,—In one of your back numbers, I note the English Coach Builders' Association are looking about for a substitute for the English ash.

There are many good timber trees in our jungles that have all the characteristics of the ash, and it would be well in these days of small crops to make use of the timber.

The Vengai (*Pterocarpus Marsupium*) or Kino tree affords excellent timber, but one drawback is that it can't be used for lintels of doors, &c., as it discolors the whitewash. The blood-red juice of this tree on exposure to the sun soon hardens, and is the "Kino" sold in shops. It is used in colouring port wine also. Another is the "Ironwood tree" (*Mesua Ferrea*), Tam. *Irul*, Can. *Naga Sampage*, which is a very hard timber, and owing to the difficulty of manipulating the wood is seldom used.

W. D.

DECIDUOUS E. LITHOSPERMA.

Sir,—I had an idea that Mr. Nelson held that *E. lithosperma* was a non-deciduous tree. It may be in his district, and also when once established. But I noticed a letter in your columns stating that in Mysore most of the *E. lithospermas* were almost bare of leaves, and in this very hot, "hot weather," too. On the Nilgiris the same complaint is being made.

A good deal of dissatisfaction, too, is caused by the large proportion of thorny trees that come up from his seed. I do not deny that his seed is, perhaps, the best available, but when he calls it the only "thornless" variety, and a goodly lot turn up covered with thorns, well—people grumble. A change in the wording of his advertisement, somewhat in this manner, —— rupees per pound; guaranteed germination——per cent.; guaranteed thornless——per cent. of germinated plants, would remove all misapprehension. A note of explanation on the "non-deciduous" habits of the tree would also be useful.

Evergreen.

A SNAKE STORY.

Sir,—It will interest many of your readers to know that a hamadryad (*Ophiophagus elaps*), nine feet long, was killed yesterday by my overseer on Kasier estate, Aracood, Kil Kotagiri (elevation 4,000 feet). It appeared of abnormal girth, and on cutting it up to preserve the skin, a large snake came in evidence, and on my visiting the estate to-day, as I could not identify it with certainty from description given me, I had the remains of the hamadryad exhumed, and recognised the swallowed snake, which was still in good preservation, as a small python (*P. molurus*) measuring 7 in. in girth and 5 ft. 1 in. in length.

The hamadryad is the first specimen I have ever seen or heard of this side of the hills during a residence of 25 years. When encountered, I am told, it exhibited all the aggressiveness for which it is so dreaded, and had it not been satiated with its python meal, it is probable it would have given chase when disturbed.

"YOUNG PLANTS DYING."

Sir,—In your issue of March 5th, "Planter" writes: "It not unfrequently occurs that young plants which have successfully stood their own throughout the hot weather die off after the first spring showers . . . To what cause do your most experienced friends attribute such results"?

A possible solution of the problem may, I opine, be found in the theory of "cell rupture." A plant during the dry weather remains almost inactive,—practically ceases to absorb or assimilate nourishment and, in short, winters. As soon, however, as the spring showers fall, moisture is supplied, the plant absorbing this in quantities in excess of its capabilities to distribute the same through its tissues, sustains what may be designated a "cellular rupture," resulting in death synonymously, from a physiological point of view what would occur to an individual who, having undergone starvation for an extensive period, all at once satisfied to the full his craving for food.

D.

[We hold this to be a likely explanation. The action of "frost-bite" on plants is attributed to the same cause, *i.e.*, cell-rupture, though due to a different agency, *i.e.*, the sudden expansion of the cell-liquid by the warmth of the sun.—Ed.]

COFFEE IN HAWAII.

Sir,—With reference to your very interesting paragraph in your issue of the 26th instant on "Coffee Prospects in Hawaii," can you tell your readers, or can any of your readers tell you, what I think will be even more interesting to the majority, that is whether there is any demand at all for the planter with experience but *without* capital, *i.e.*, superintendents?

I imagine, from my own experience and from the advertisement pages of *P. O.*, that there are more than a few bachelors like myself who would not be at all unwilling to exchange South India for Hawaii if there were a reasonable salary and climate to be obtained in the latter place.

The nice little sum showing a profit of 21 thousand dollars, not to speak of a valuable property, at the end of seven years, means a capital of, say, a lakh and-a-half in rupees, and even then one does not know if the building of a bungalow, &c., is estimated for,—it hardly looks like it.

I am sure many would like to hear much more about Hawaii,—the labour, the climate, the kind of jungle, and all the conditions, especially the price of food, even if every one has not a lakh and-a-half.

I note that the curing is apparently done on the estate. Is the machinery necessary for this included in the seven thousand dollars estimated for the first year? *Can* the first year's estimate include machinery, building, &c., besides felling, clearing and planting with all that that entails? All these are expensive works, at any rate here! The coffee is evidently intended to be planted at once, as two cwt. per acre is estimated for the third year! I hope that information on this most interesting subject will be forthcoming.

Cure.

[We trust that the Editor of the Hawaiian *Planters' Monthly* will be able to give the requisite information in his journal. "Cure" should address his enquiries to the British Consul, Honolulu, Sandwich Islands.—Ed.]

GENERAL ARTICLES.

RHEA IN INDIA.

THE last published proceedings of the Agri-Horticultural Society India contain the following correspondence on the subject of hea cultivation in this country. It will be noticed that there is a eat difference between the results obtained at the Saharanpur otanical Gardens and those obtained elsewhere:—

Letter from the Secretary, Rhea Fibre Treatment Company, mited, in continuation of former correspondence. "In further ference to your letter of the 31st August, perhaps the best way replying to the same will be to send you the enclosed extract from letter we have written to Mr. Whitehead, which we think will eak for itself, and in which we have explained our statement that were willing to pay a higher rate for ribbons of approved quality. e hardly think it is possible that Mr. Gollan refers to the ribbons mply stripped from the cane and dried, as we require them, for e following extract conveys an impression of a distinctly opposite aracter:—

'Our highest return is a ton of wands per acre, weighed after ripping off the leaves, which yield from 3 per cent. to 7 per cent. ribbons, *according as they are well cleaned and scraped or not.*'

"From information supplied to us by those who have cultivated, d are cultivating Rhea plants, the plant once established, an acre land will yield about 25 tons of green stalks with the leaves on: ese stalks will produce from 5 per cent. to 7½ per cent. of dried bbons, or, calculating on the lower figure, 1¼ tons of *dried ribbons* r acre, and we, therefore, venture to suggest that Mr. Gollan's lculation of yield should be carefully and independently tested fore being accepted in its entirety.

"We trust these opportunities of correspondence, which you are ood enough to afford us, may be the means of giving information hich will act as an inducement for practical experiments and vestigations being made, in order to ascertain the actual yields different localities, and conduce to the development of the dustry, and profit to the Indian ryot."

(*Extract from letter to E. C. Whitehead, Esq., dated 24th September.*)

"The 'slightly higher prices,' to which you draw our attention, eans that if we were quoted instead of £10, £11, or even £11-10*s.*, e might feel disposed to pay this price for a very good ribbon for short time, so as to encourage the cultivators and to give them a mewhat wider margin during the first year or two of their ltivation, and which must until they, from practical experience, rive at the best way of going to work, be more 'or less in the ture of experimental cultivation.'"

The above letter was sent to Mr. Gollan, Superintendent, Governent Botanical Gardens, Saharanpore, who wrote as follows:—

"In reply to your letter of the 19th instant and enclosure, from e Rhea Fibre Treatment Company, I am sure of the figures I sent ou on the subject of Rhea, as far as this part of India is concerned. is simply folly to think of growing the plant for profit in the mparatively dry districts of Northern India. I believe it could e grown with profit in warm, moist districts in Assam, in some rts of Bengal, and in some of the Southern and Western districts India; but in Northern India the climate is too hot, and dry ring the hot months, and too cold during the cool months, for the ant to wand freely. Our only crop, which is worthy of the name, the monsoon crop, and it, at its best, is light compared with what e plant is capable of producing in districts with a moist equable opical climate."

PROFESSOR PLATEAU ON FLOWER ATTRACTION.

PEOPLE have long held the romantic fiction—as it is now roved to be by Professor Plateau of the University of Ghent —that flowers deck themselves in beautiful colours to attract e wandering bee and flighty butterfly. We watch the glorius blossoms flashing in the sunlight or gleaming star-like at nightfall, and we imagine all this beauty is to attract bee, butterfly or moth, a direct appeal to their artistic sense. Mr. Grant Allen, in his charming little book, "The Story of the Plants," tells us: "*that* is in fact what beautiful flowers are for —to attract the fertilising bees and butterflies." Sir John Lubbock also has led us on to theorise concerning the origin of varieties of flowers, and trace to the insects, which apparently distinguish between colours and evince likes and dislikes in the matter, the advantage some varieties have in the struggle for existence. Even individual flowers may become peculiarly specialised: thus, the nectary may become so deep as to be accessible only to insects with long proboscis, as bees to the exclusion of flies, butterflies and moths to the exclusion even of bees, it may be even to some particular species only. Mechanical adjustments are also to be found in many of the more specialised types. Witness the stamens of the sage, which are rocked forward by the bee on entering the flower so as to dust his back with pollen just where it will be rubbed off upon the stigma of the next flower. The most extraordinary variety and complexity is, however, that presented among the orchids. How some flowers, *e.g.*, (Stapelia, Rafflesia) attract the services of flesh-flies by the odour and even colour of carrion; how others like Arum and Aristolochia may entrap and detain the fertilising insect until well dusted with pollen, are examples which can but be mentioned.

Now comes M. Felix Plateau, the Belgian savant, and after an exhaustive study of the question of how flowers attract insects, gives us a theory diametrically opposed to conclusions of attraction previously arrived at. In the course of his experiments he covered the flowers of a single dahlia with green leaves. In some cases the petals alone were hidden, in others the whole flower. The insects visited them as assiduously as before. Various experiments followed, of which the feature was to disguise the flower or render it inconspicuous. The gaily coloured parts were removed or hidden, but with the same result. The insects continued to visit them. The Professor gave the subject long and patient consideration and experiment, and arrived at the conclusion that colour plays a very subordinate part in the attraction of insects. He discovered that insects pass from colour to colour of the same species of flower—from blue to purple, rose or white cornflowers, from red to yellow, purple, scarlet or white single dahlias, from the brilliant flowers of the scarlet garden flax to the equally brilliant blossoms of the common blue flax.

These experiments over, Professor Plateau developed his interesting theory, viz, that insects by their keen sense of smell detect the presence of the honey, and are not guided to it by the appearance of the flowers. There are certain flowers of gaudy colouring that are rarely visited by insects. These when provided with honey were rendered attractive. The scarlet geranium was amongst those chosen for this experiment,

W.

and some of the flowers were given a little honey. In the course of an hour eight bumble bees had visited the flowers, passing over without alighting on those blossoms that did not contain the nectar. Phlox, Japanese anemone, the larger bindweed and others were then submitted to the test, with identical results. The next experiment was to remove the honey from flowers naturally containing it, and then to watch the effect. Although a difficult operation, it was successfully performed, and the result was as anticipated. The insects ceased their visits. These same flowers were then supplied with honey, and then they once more proved attractive. Professor Plateau made the discovery that the anemophilous plants, *i.e.*, those that depend on the wind for fertilisation, and have inconspicuous flowers, can be rendered attractive by providing them with honey. He also had his attention called to the species of plants with green, greenish, brownish flowers that yet have the power to draw insects—containing as they do honey. There are about ninety in all, amongst which are ivy, asparagus, sycamore, wood sage, figwort, etc.

The Professor then proceeded to construct artificial flowers, such as the lilac, forget-me-not, foxglove, etc., and placed them, provided with honey, amongst the natural flowers; but in no case were they visited. When, however, he made artificial flowers from natural leaves and gave each a store of honey, they were constantly visited, though their appearance was decidedly unnatural. Professor Plateau's theory, then, stands thus:—"Insects seem to care little for the presence or absence of floral parts or brilliant colours. That which they desire is pollen or nectar, and they are guided towards this pollen or this nectar in a very subordinate way by sight, but, on the contrary, in a very sure way by another sense, which can only be smell."

CULTIVATION OF PARA RUBBER.

(*Continued from page* 134.)

Rate of growth. The tree grows very rapidly in height. The original trees, planted at Henaratgoda in 1876, were about 30 ft. high and 14 in. in girth two years later. In 1882 the largest tree was 50 ft. high and 25 in. in girth at a yard from the ground. The girth of this largest tree was taken annually after this with the following results:—It was 30 in. in 1883, 36 in 1884, 43 in 1885, 49 in 1886, 53½ in 1887, 60 in 1888, 65 in 1889, 69¾ in 1890, 73 in 1891, and 79½ in 1893. The girth of the largest tree measured in Brazil by Mr. Cross was 82 ins.

The measurements above given are those of the largest tree. More useful data for scientific and practical purposes are obtained by taking the mean girth of all the trees on a considerable area. This was done in January, 1897, on the plantation made at Henaratgoda in 1876. This now consists of 45 trees, about 30 feet apart. The girth was taken at the height of the eye, about 5 feet 6 inches above the ground. The largest tree was 7 feet 5 inches, the smallest 2 feet 1 inch in girth. The mean girth was 4 feet ⅓ inch.

In the plantations made by the Forest Department near Ratnapura measurements were taken in December, 1894, of the mean girth trees at 3 feet from the ground, with the following results:—

At Edangoda	(4 yrs. old),	mean of	100 trees	12·96 in.
Do.	(3 yrs. old),	do.	50 trees	8·75 in.
Do.	(2 yrs. old),	do.	20 trees	4·96 in.
At Yattipowa	(3 yrs. old),	do.	108 trees	9·37 in.
Do.	(3 yrs. old),	do.	108 trees	9·13 in.

The larger measurement at Yattipowa is that of trees on t western slope, the smaller that of trees on the eastern slope. T difference appears to be due to the fact that the latter are expos to wind.

Tapping. The yield of rubber from very young slender trees is too small to make their tappi worthwhile, and it is best for many reasons to abstain from tappi a tree until it has reached a girth of two feet. In a large plantati he girth of the trees always varies between wide limits. A few tre may be fit to tap after the sixth year, and in every subsequent ye more and more trees will reach the size necessary. In favourab localities the bulk of the trees should be in bearing before the e of the eleventh year. The results of the experiments hitherto ma at Henaratgoda go to show that it is inadvisable, having regard the future, to tap trees of less than two feet in girth, but it is st an open question whether the minimum size of tree for tappi should not be fixed even higher. This, however, would of cour necessitate longer waiting for the return, as the mean rate increase of girth in trees of this size is only about three inch per annum.

The methods of tapping and of coagulation of the rubber employe by the native collectors in Brazil and elsewhere are rough, wastef and inefficient, and there is great room for improvement. Exper ments are being made at Henaratgoda to test methods of tappi and coagulation, and their results will form the subject of a subs quent circular. At present we shall only describe the method whi has been employed for some years in the tappings carried on Henaratgoda.

The requisites for the work are a ¾-in. chisel, a wooden mallet, number of clean cocoanut shells, each cut in two so as to form sm basins, a knife, and a supply of clay and water with which to for the gutters round the trees.

The tree is first carefully and lightly shaved with the knife from height of about 6 feet down to the ground, so as to form a perfect smooth surface. Only the outermost layers of the bark must b removed in this process, otherwise the tree will be injured. Whe the shaving is completed, the tree may be polished by hand or car fully brushed. The great object in view is to obtain a smooth an clean surface, over which the milk can run easily, without becomi contaminated by small particles of bark or other rubbish, as th market value of rubber depends on its cleanliness.

A clay gutter is next made round the tree about six inches abo

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

the ground, so arranged as to catch the milk which will trickle down the tree and empty it by two or more spouts into as many clean cocoanut shells placed below. Three shells are sufficient for a tree of 2 ft. 6 in. girth, but larger trees may require four or five. The gutter is made by rolling rather wet clay into a sausage form, between the hands, and then pressing it on to the bark, and forming the channel against the bark by aid of a wet finger. The gutter must not be allowed to dry before the tapping is begun, otherwise the rubber will be contaminated by particles of clay; neither must the gutter be so wet or irregular as to allow the rubber to be dirtied.

Incisions may now be made in the bark with the mallet and chisel, commencing near the top of the cleaned portion.

A V-shaped cut is made in two strokes. The object to be aimed at is to make these cuts to such a depth as just not to reach the wood. They should stop in the bark close to the cambium, as the vessels which contain the rubber occur only outside, but very close to the cambium. If the cambium is not injured, the wound rapidly heals, but if the cut penetrates this layer, and enters the wood, the healing of the wound is much slower, and at the same time risk is run of introducing parasitic fungi into the wood, which may cause much damage. Injury to the wood also causes a check to the upward flow of sap, and thus to the growth of tree. Considerable practice is required before the chisel can be habitually driven in to the exact depth necessary. In dealing with a number of trees it will be found most economical and satisfactory to keep separate coolies for each of the various operations required, as they all need much practice.

As soon as the cut is made, the white and very sticky milk commences to flow. A second V-shaped incision should be made about a foot below the first, and others at similar distances down to the gutter at the base of the tree. Another set of incisions may then be made parallel to the first, at about ten or twelve inches from them, and other vertical rows of cuts may be made if there be sufficient room for them. On a tree of 2 ft. 6 in. in girth, four vertical rows of cuts may be made without serious injury.

As each cut is made the milk flowing from the cut above it should be guided downwards to it along the bark by means of a twig, otherwise the milk is liable to be wasted by dropping to the ground from projecting portions of the bark.

The bulk of the milk, especially in large trees or trees which have not been recently tapped, ultimately flows into the cups at the base of the tree. These should be kept covered in such a way as to prevent dust or other rubbish falling into the milk. As soon as the milk ceases to flow into the cups, these are removed to a warm place, and in a few hours a cake of solid rubber can be removed from each, which should be kept in a dry place until it has become properly dry all through. The remainder of the milk dries upon the trees in the form of long strings, which are stripped off and rolled into balls. The whole of the rubber when dry is now ready for market. The most suitable times of the day and of the year for tapping are still the subject of experiment. The most satisfactory results have, on the whole, been obtained by tapping in the drier parts of the two monsoons, *i.e.*, from January to April and in August and September. The tapping should be done on dry days, otherwise it is difficult to prevent dilution of the milk and to dry the rubber.

The tappings may follow one another at intervals of a week for about four to eight weeks. The second tapping gives a much larger yield than the first, and the third and fourth tappings are usually very productive. In a series of experiments made during 1897 on trees of about 2 ft. mean girth, the average yield per tree of the successive weekly tappings was as follows:—

	oz.
First week	·73
Second „	1·4
Third „	·97
Fourth „	·80
Fifth „	·67
Sixth „	·52
Total ...	5·17

Yield. The statements as to yield of rubber found in books of travel and popular articles are very unreliable, and experiments are being made to test the whole question of yield. The late Dr. Trimen commenced in 1888 to tap one of the original trees at Henaratgoda, then nearly twelve years old and 50½ in. in girth a yard from the ground.

It was tapped on seven days between 25th January and 15th February, yielding 17¼ oz. of rubber, on six days between 20th July and 29th August, yielding 7 oz., and on four days between 6th and 20th December, yielding 4⅓ oz.; a total of 1 lb. 12¾ oz. The same method was followed in alternate years, with results as shown below—

1888	... 1lb. 12¾oz.	1894	... 3lb. 3 oz.
1890	... 2 „ 10 „	1896	... 3 „ 0¼ „
1892	... 2 „ 13 „		
		Total	... 13lb. 7oz.

The average yield of this tree from the twelfth to the twenty-first year is thus almost 1½ lb. per annum. This result is very good, and if all the trees of the same age yielded as much rubber, the success of the cultivation would be assured. It should, however, be noted that the girth of this tree in 1888 was larger than the mean girth of the whole plantation, as mentioned above, in 1897, and that therefore this yield, if the tree tapped be accepted as a fair sample, represents rather the result to be expected after twenty years, by which time the average girth of the trees should be equal to the girth of this one at the time its tapping was commenced. The trees in question are about 30ft. apart, *i.e.*, 50 trees to the acre. These data thus indicate a yield of about 90lb. of rubber per acre in the twentieth year, a result insufficient to make it worth the while of private planters to take up rubber cultivation.

It seemed probable that better results might be obtained by tapping younger and smaller trees more closely planted, and experiments were therefore begun in 1896 on a younger plantation of trees at Henaratgoda. The mean girth in January, 1897, taken at 5ft. 6in. from the ground, of 225 of these trees was 2ft. 4½ in. The figures already given for the average weekly yield represent the mean results of the tapping of 27 trees of a mean girth of 1ft. 10½ in., six inches less than the mean girth of the whole plantation. From six consecutive weekly tappings of each, a mean yield of 5·17 oz. per tree was obtained. This represents a yield of 97 lb. per acre of 300 trees (12 ft. apart). If the trees tapped had been of the same mean girth as the whole plantation, the yield would probably have been at the rate of about 120 lb. per acre. Further, only six tappings were made, and the trees, after a rest of a few months, would probably have stood three or four more tappings whose yield might have been at the rate of 30 or 40 lb. per acre.

No record, unfortunately, was kept of the date when this plantation was made. It is probably twelve years old at least. The sandy soil at Henaratgoda is unfavourable for Para rubber, and in better soil the trees would probably reach this mean girth in ten years or even less. It would seem, therefore, that if this cultivation is taken up in favourable localities, a yield of about 120 to 140 lb. of rubber per acre may be expected after the tenth year. This estimate is, however, liable to modification by the results of experiments which are still in progress.

Cost of opening plantations. The following estimate of the first year's cost of opening a plantation of 300 acres of forest land with rubber was prepared by Mr. F. Lewis, Assistant Conservator of Forests, Colombo:—

	Rs.
Felling and clearing at Rs.12 per acre ...	3,600
Lining, 10ft. by 10ft., at Rs.2 per acre ...	600
Holing, at 75 holes per cooly at 40 cents ...	697
Filling and planting and carrying plants from their nursery to holes, 300 per cooly at 40 cents.	175
Draining: 300ft. of drains per acre at 1 cent per foot run	900
Lines for coolies: 1 shed of 10 rooms of 12ft. by 10ft., mud walls, and battocalla roof, at Rs.30 per room	300
Roads for inspection, 2 miles	160
Plant nursery, including watering	150
Weeding, at Re.1 per acre per month ...	3,600
Cost of surveying lines round plantation, say ...	75
Contingencies, such as special work, bridges over streams, or supplying vacancies, &c. ...	250
Salary of assistant	1,000
Tappal cooly	120
Tools	300
Total ...	11,927

This represents an average of Rs.40 per acre. A return of Rs.4,200 is estimated to be obtained by the sale of timber and firewood from the land cleared. This should suffice to erect the assistant's bungalow and leave a small margin for contingencies.

To this estimate private planters must add the cost of land and of seed (about Rs.20 per 1,000). These items will probably bring up the total cost for the first year to at least Rs.125 per acre. As a matter of fact, 300 acres are more than can be opened in one year, as the number of seeds required will be at least 160,000, which amounts to nearly two years' crop of the trees in the Botanic Garden.

For the second, third, and fourth years Mr. Lewis estimates the expenditure on weeding and supplying at Rs.12, Rs.8, and Rs.12, respectively. Assuming that the expenditure in the years following is at the rate of Rs.5 per acre, the cost of the plantation up to and including the tenth year might work out as follows :—

	Rs.
Cost of land, 300 acres at Rs.75	22,500
Cost of seed, say	3,600
First year's cost as above	11,927
Weeding and supplying, second year	3,600
Do. third year...	2,400
Do. fourth year	1,500
Do. fifth to tenth years, inclusive ...	9,000
Salary of assistant, second to tenth years, inclusive ...	9,000
Tappal cooly and tools, second to tenth years, inclusive...	1,250
Total ...	75,777

Allowing interest at the rate of 7 per cent. on all money expended up to the end of the tenth year, the outlay upon the plantation will amount to at least Rs.1,10,000, or Rs.366·66 per acre.

Return. The value of Para rubber in the London market varies between two and four shillings per pound, according to the quality of the rubber and the state of the market. Of the rubber which has been collected in the Botanic Gardens and sent home for valuation, a large proportion has been valued at almost the highest market price then ruling, but a considerable proportion of the rubber is always of inferior quality, being mixed with particles of dirt. If we estimate the average value of the crop at 2*s.* per pound, and the yield in the tenth year at 100lb. only per acre, the return in that year will be £10, or say Rs.150 per acre. The cost of harvesting should not be more than Rs.50 per acre, including carriage to London. This leaves a margin of Rs.100 per acre, representing a return of 27 per cent. upon the original outlay; if 12 per cent. be allowed for contingencies and the usual vicissitudes of a tropical cultivation, there remains still a prospect of a good return on the capital expended.—John C. Willis, *Director, Royal Botanic Gardens.*

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (March 18, 1898) says :—Larger supplies have been brought forward in Public Sale this week, and these met a poor demand at declining prices for all except the finest qualities.

About 2,600 bags East India were offered, out of the S.S. "Dido," which has only just arrived after a very slow voyage; the bold colory grades attracted good competition, but mixed and greyish descriptions barely realised valuations.

Central American kinds received little attention, and were with difficulty disposed of at a decline of 3/– to 4/–, whilst a large proportion had to be bought in.

Heavy receipts caused a further fall in Futures this week, and at the close quotations are 1/– lower than our last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending March 16th, 1898, says :—Bank rate 3°/₀. Bombay Exchange closes at 1s. $3\frac{15}{16}$d. Brazil Exchange $6\frac{9}{32}$d. Rupee paper $3\frac{1}{2}$°/₀ $63\frac{1}{4}$. Silver $25\frac{5}{8}$d. per oz.

This market closes very flat and considerably lower for Central American kinds, especially London cleaned, which are difficult of sale at an irregular further decline of 3s to 4s per cwt. East India continues steady for the better qualities, ordinary being only partly sold at 1s to 2s decline. Brazil markets dull.

Daily receipts averaged 13,700 bags in Rio and 14,800 bags in Santos.

Futures have ruled weak with a small business doing at a further decline of 1s to 1s 3d per cwt., viz. :—Good average Santos in Havre, May delivery, fcs. 34.25, in Hamburg pf. $28\frac{3}{4}$, and No. 7 low ordinary Rio in New York $5.10.

To-day's London official quotations are :—

	March	May	July	Sept.	Dec., '98.
Santos ...	27/9	28/–	28/3	28/9	29/3

† S. America. * Probably the bulk of the Tea exported to Germany was for Russia.

Russia, which is largely supplied *viâ* Germany, shows a most encouraging increase. South Africa is coming more prominently forward, while Holland continues to make progress. Chile is also an important market. To the United States, Canada and Turkey, shipments go largely direct.

Indian. For good liquoring Teas rates were fully maintained, but for poor descriptions prices were again lower.

Week's av. of Tea sold on Garden Account, 1898, 20,586 pkgs., av. 8·20d. 1897, 18,397 pkgs., av. 9d.

TO PLANTERS AND GROWERS OF PRODUCE.

What others do ! !

It is well known that there are Merchant Houses that, although they accept Produce for sale on **Planter's Account,** they, on the other hand, are also **Purchasers on their own Account.**

What we do ! !

It is evident that the services of such houses are not wholly and unreservedly at the disposal of their correspondents. We on no account enter into competition as **Buyers against Planters,** but deal with each separate shipment on its own independent value; correspondents may, therefore, rest assured that **Produce** sent to us will be sold upon its merit, and not used to bolster up inferior qualities.

Business Area :—

We do not confine our business to any particular part of the world, but receive **Produce** from all over the globe, and are in touch with every market for **Produce.**

Samples and Reports :—

On receipt of samples, particulars of the class of **Produce,** and the quantity that can be shipped, a report shall be forwarded, giving full particulars as to market value, demand, &c.

How we Pay :—

We can secure more money for the Planter and Grower of **Produce** than he can obtain by local sale, and, although in the latter case he may at once secure cash, we are quite ready to meet this, possible, advantage to the **Planter,** and by our system of negotiation of drafts drawn upon us against **Produce,** and willingness to pay freight on approved shipments at this end, the **Planter** will obtain a very substantial portion of cash, and further will be quite certain to receive the full **Market Value** of the **Produce** shipped to us.

Promptness :—

All enquiries will be answered by return mail, and upon arrival of shipment every expedition will be used to turn into money the **Produce** sent us.

Markets :—

We can find a market for any **Produce** from any country on the face of the earth. Put your business in our hands and be certain of getting full value and prompt action.

Bouverie House, Salisbury Square, London, England.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 11 and 12, Second Line Beach, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 22nd April, 1898.

Season Reports should be sent to the Printers, Messrs. Addison & Co., direct, and not to *Planting Opinion* Office.

Coorg.

Polli Betta, 12*th April*.—*Weather.*—No rain except a few cents a couple of weeks ago. Another rain cycle commenced on 10th, but no rain has fallen here yet. Other parts got good rain from 26th to 30th. *Crops.*—Estates which got the rain had a fine blossom out between 4th and 6th. Other places, spike on the whole still good, but rain badly needed. *Public Health.*—Much improvement. Influenza travelling to other parts now.

Nilgiris.

Coonoor, 13*th April*.—The long expected rain did its very best to pay us a visit last night, but a mile or so north of Coonoor we only got a couple of cents or so. Ooty probably got a shower. The tension of feeling regarding the season's blossom is great, for if timely rain falls, crops this side will be excellent. Tea is hanging fire a lot owing to want of rain. There is nothing of interest to record. The blessed railway is making record progress up the ghaut. It is seriously asserted in authoritative circles that June *next* year will see the first train running at least as far as Burliar.

Kil Kotagiri.

13*th April*.—*Weather.*—No rain yet, all the estates suffering badly and spike burning off, the last blossom suffering badly about half has gone. *Public Health* very bad; a lot of fever and small-pox. *Interesting Items.*—We are now going to get an Apothecary for the district, each estate paying 12 annas per 1,000 trees towards his pay, medicines, etc. A meeting was held, and everyone has agreed to the 12 annas plan except one. *Labour.*—More than sufficient for hot weather work; some planters want to know what to do with their women coolies. Grain still expensive.

THE KEEPING OF ACCOUNTS.

To many of our readers the very heading will be enough, and the page will be turned over hastily to another and less dismal subject. For to the ordinary layman, who gropes among his accounts with weariness and stumblings, the task of keeping accounts is one of the most hateful of his life. While all goes well, and expenses are well below the income, while bills are easily met and the balance at the bank grows apace, accounts are seldom bothered with. All is so simple and pleasant, fumbling with the figures were surely time ill-spent, unprofitable and wasted. Thus think many. But when liabilities increase, cash grows scarce, and the balance at the bank is only a name; then comes the inevitable task of grappling with the accounts. They may be intricate, blurred and tangled almost past solution, but however difficult and weary the work, the labour of setting the tangled skeins aright in time, is felt with overwhelming force to be the only alternative to failure, dark failure, with the ill-boding Court of Bankruptcy lowering in the background. Had the prime importance of keeping the accounts straight been recognised at the first, the dangers and difficulties of coming failure had been, in more cases than the public dream of, successfully averted.

For what is the object sought to be attained by keeping one's accounts in perfect order? Simply to know exactly, and at any given moment, one's financial position. The importance of this knowledge is well set forth by Mr. C. E. Ross, of the P. W. D. Accounts Department, author of a useful little work on accounts.* Every person knows, or thinks he knows, what money is; but few know, or even care to know, how to account for it properly. Yet the latter knowledge is almost the more important of the two. These are two *desiderata* in regard to money. The first of course is to get it: the second, to know how to account for it when you have got it. Everyone can understand the first; but many neglect the latter altogether. Yet if they but knew it, the latter would help them to get more of the first, and to keep it, too. The attainment of wealth is dependent to a very great extent upon ability to account for it. Those who systematically ignore their accounts are, as likely as not, on the high road to bankruptcy.

It is difficult to understand why accounts should be neglected, except from one reason only, and that is, want of knowledge how to keep them. For a man who fails to account for money entrusted to him by his employer is rightly considered dishonest towards his employer, and is very properly punished for his offence. Though no direct punishment may be meted out to the man who neglects to account for his own money, and is thus dishonest to himself, the blame is still there.

Having cleared the ground a little, and presumably interested our readers in the subject, let us return to Mr. Ross' work and try and present in as clear a manner as possible the first of the principles that govern all sound book-keeping. The difficulties that attend the art are not so huge as many people fancy them to be, but again are by no means so slight as beginners will imagine. First in importance is the principle of classifying all transactions under their proper heads, of which these are two main ones—Capital and Revenue. A person opening his books say from the 1st of May, will have to first make an accurate list of the various property he owns, with the value attaching thereto. To these, he will add whatever sums of money are owing to him by private persons, banks, or as salary up to the end of April. These will constitute his assets. He must then make a corresponding list of all the debts he owes, bills, loans, and so on to the same date. These constitute his liabilities, which let us hope will be far smaller than his assets! The above two lists will form his balance sheet, and must be entered under the head of Capital. The second main head, Revenue, is divided into income and expenses, and entries will be made each month under these heads in that month when these transactions are due. Thus all the bills due for May, servants' wages, etc., must be entered in May, while sums paid for bills and wages due in April or previously must be entered as a capital item. The object of this is, of course, to keep Capital and Revenue perfectly distinct, to know exactly each month what one's current income and expenditure are (including debts due to one in that period and bills incurred by one in that month,) and thus to keep touch with the growth or fall in one's original capital.

With this we shall take leave of the subject this week, but hope to return to it and go more into detail than has here been possible. In conclusion, let us reassure those of our readers who may purchase Mr. Ross' work, lest they should be unduly scared at the very numerous sets of forms and headings that he recommends. They are by no means all necessary: three of the awful number of the twenty-three books recommended will be found sufficient for all purposes.

* "How to Keep Accounts," by C. E. Ross: Commercial Press, 24, Free School Street, Calcutta; or Thacker, Spink & Co., Bombay. Price Re.1-4.

NOTES.

High price for Tea land. It is interesting to note in a Ceylon contemporary that the highest price ever paid for tea land in Ceylon was recently paid for the Holbrook estate, Dimbula district. This record figure was as high as £120 per acre. It should be remembered, however, that the estate has other and very valuable attractions as a residential estate, besides its capabilities as a tea estate.

Auction sale of Para rubber seed. Some 70,000 seed from the Botanical Gardens of Ceylon, of this valuable variety of rubber, were recently put up to auction in Colombo. The prices realised were from 25 to 29 rupees per thousand seeds delivering in August. One of the conditions of purchase was that the purchasers should enter into a written agreement to the effect that the seed would be planted in Ceylon, and that the seed would not be re-sold.

Messrs. Geo. White & Co's. Tea Review. This firm's interesting Annual Report for last year has reached us. The main feature of last season's teas was the superabundance of plain and characterless teas, the low price for which did not stimulate consumption in the usual manner. Labour troubles in England and the phenomenal

activity of cacao vendors are alleged to be among the important causes for the depression. Finer plucking and more careful manufacture should be the guiding principles for the present season.

Ceylon and exchange.

Thus writes the *Ceylon Observer*, and heartily do we echo its words :—"We congratulate the local Chamber of Commerce on the manner in which an indispensable, but by no means welcome, duty has been performed, in protesting against the currency policy of the Indian Government. We think the outcome of yesterday's (March 28th) meeting will compare favourably with the recent action of any of the Presidency Chambers whether of Calcutta, Bombay or Madras. In the first place the Ceylon Chamber, representing by far the major portion of the importing interests of the Colony, had no difficulty in declaring, and that too without a single dissentient, that in the matter of an honest rather than an artificial currency, the interests of the producers claimed the first and by far the greater degree of attention. Now, if this be true of little Ceylon, how many times more must it be the case in regard to India, if its industries and trade as a whole are fairly considered? And yet we have had many of the merchants of the Presidency capitals by no means rising to the occasion and taking that wide, liberal and just view of the situation which the interests of the silent millions of Indian producers absolutely demand."

Upper India planters and exchange.

South Indian planters will learn with pleasure that the apathy which has till recently characterized the attitude of the Indian Tea Association on the question of exchange, is likely to change into a better appreciation of the position. At a General Committee meeting of this Association, held at Calcutta on the 14th March, the following item occurs :—

"In his letter of 18th February, the London Secretary drew attention to a press telegram which stated that the 'Planters' Association of Southern India have addressed a strong protest to the Government concerning exchange, and demanding the re-opening of the mints, urging that increased trade would outweigh the Government loss,' and he asked for the views of this Association on the subject.

"After discussion, the Secretary was instructed to inform Mr. Tye that the General Committee entirely agreed with the arguments put forth by the Southern India Planters' Association, and they would be prepared to take the matter up."

It is about time they *were* "prepared to take the matter up." The Indigo planters, too, should lose no time in following the lead given them. It seems incredible that a combined movement by the whole planting interest in India has not before been set on foot. In a little while protests will be too late, and the disaster that threatens Indian producers will have become an accomplished fact. We shall then be treated to any amount of wisdom after the event.

The proof of the pudding.

Many and interesting have been the contributions published in these columns on how to prepare the best recipe for the leguminous coffee pudding. Sceptics of the excellence of the recipe were curious to know more about the actual taste of the dish, and the results already observed on the coffee treated to the dainty dish. The opportunity they have been awaiting is now at hand, for Mr. Nelson is now anxious for planters to come and see for themselves what coffee can do in its last haunts in South Travancore. He writes: "Cannot you persuade some of your coffee planters to come and have a look at my *Erythrina lithosperma* coffee. The crop is incredible, and I have never seen such regular clusters and trees such a mass of crop. A ton an acre is nothing to what some of the trees have. *Erythrina lithosperma* and what I call my 'A. G.' system ought to mean fortunes in other districts if they can do the trick in South Travancore, where leaf-disease has practically destroyed the coffee. What ought it not to do where leaf is not half so bad? My pudding is practically in the eating stage and my 'Rêve d'or' a *fait accompli*. Rain alone is needed to keep the berries on the trees."

What say holiday trippers? A week's holiday could easily be worse spent than running down to Shencottah and seeing what the now famous *Erythrina lithosperma* shade can do, if properly managed.

Tanning barks.

Extracts of bark are being more largely imported and used by tanners, says the *Produce World*, the value of those received from the United States, principally hemlock bark, that of the spruce fir (*Abies Canadensis*), which contains about 14 per cent., averaged in the five years ending 1894, £40,000. In 1894 this extract was imported from Canada to the value of £24,600. Many other bark extracts are imported and used—chesnut wood, oak wood extracts, &c.

We are likely to get very little more mimosa, or wattle bark, from Australia, there being such a demand in the local tanneries. It is estimated that at least 14,728 tons of Victorian bark were produced in 1893, of which 10,900 tons were used in the local tanneries of the Colony, and 2,828 tons exported. New South Wales imported, in 1894, 74,580 cwt., a large proportion being obtained from Tasmania. The exports of this bark from Tasmania have fallen from 12,000 tons in 1883 to 5,400 tons in 1894. The exports from Adelaide keep pretty steady at about 4,500 tons yearly.

In the great deficiency of tanning substances, every new discovery may be hailed with satisfaction, and this is also used as a dye-stuff in Kashmir. It is mentioned in the *New Bulletin* for January, and is said to be the root of *Geranium Williekianum*. From the analysis made by Mr. Proctor, of the Yorkshire College, it contains 25 per cent. of tannin, and if it can be obtained in sufficient quantity it would form a valuable addition to our tanning materials. The tanning matter is about equal to myrobalams, but can the root be furnished at as low a price, coming from the Himalayas?

Kangra Valley Tea planters.

Nowhere in India is the present position of the tea-planter an extra-enviable one, but the Kangra valley as a district perhaps takes the cake for general depression. Twenty years ago its days were palmy in the land, and it waxed fat. Now the glory is all departed, and woeful indeed is the tale its planters tell. Green tea, which is almost exclusively made by native planters, used to sell for a rupee per pound barely two decades ago; now a modest two anna bit claims it for its own in Palampur. Black tea, the manufacture of Europeans, was worth in the old days one rupee the pound in Calcutta, where it barely fetches five annas nowadays. Freight, sale charges and packing cost about 1¼

annas, leaving a net 3¾ annas per lb. to the Palampur planter. The lowest cost of production for green and black teas being respectively 3 and 4 annas, Kangra valley tea is now being turned out at a dead loss.

The Kangra Association, in drawing the attention of Government to this deplorable state of things, urges that the land cesses be suspended from tea-land until the industry is on a sounder footing. It points out also an unjust and absurd anomaly in the differential rates levied on European and native holdings, the former being only taxed 12 annas per acre and the latter as much as 4 rupees. To accentuate this glaring injustice native tea land in those villages where a European owns a tea plantation are taxed at the preferential 12 anna rate! More surprising still is it to learn that if natives plant up grain land with tea, they are forced to still pay grain land taxes, which runs up 12¼ rupees per acre in some cases. What the planters want is a suspension of the Government cess and a reduction in rates of freight for tea on the State railways of the Punjab.

While doing all it can to temporarily assist the tea industry, Government would be taking a wise course in introducing some other staple more profitable than Kangra tea, which must surely give up the ghost in the very near future.

Liberian coffee.

A Sumatra planter writes to the *Ceylon Observer* deprecating the ideas prevalent that the days of paying Liberian coffee are over. There are difficulties in the way of good prices being obtained, but these difficulties can be overcome. He writes: "The curing question has been fully recognised: but few have satisfactorily overcome it. Mark this—well cured Liberian coffee will always fetch its price. One estate that I know fetched a fancy price in Europe two years ago: and has always been able to dispose of its produce at a fair market price. Another estate shipped a large parcel just before the recent collapse of the market, sold in Europe at public auction it *netted*—when the market was at smash—$29 per pikul, Singapore quotation at same date being $19—and the shippers were told that they could always get an equal price for such a sample. So much for curing. The other question is prejudice. All in Ceylon except the Podians remember the prejudice against Ceylon tea. First they said in London that brokers and merchants would not waste their time on "samples." When the samples increased in size, the *quality* was found fault with. It was trash; it was rank; it was sour; nothing was bad enough for it. And simply because they didn't know what was given them and treated Indian and Ceylon *tea* just as they had treated Chinese *chopped straw* for the previous half century. As a youngster I remember presents of Assam tea being sent home from India, 'Awfully good of dear old Charlie, you know: but ahem, ahem, &c.' 'Beastly,' was whispered; and the tea was relegated to the kitchen. And so it is with Liberian coffee. It is called nasty, rank, oily stuff. And so it is, if it is not treated properly. In the first place, as a rule, it is not sufficiently dried. It needs far more drying than Coffee Arabica. This refers especially to coffee for the breakfast table, as distinct from coffee for the market. Then it is frequently drunk too new. It wants a lot of keeping. And finally the roasting must be done slowly and very thoroughly. If these points are well borne in mind, Liberian coffee will give as fragrant a cup as any other: and the quantity will go further. In short, point for point, and step for step, it has to fight the same battle that British-grown teas had to fight a quarter of a century ago."

Mr. Carey, the well-known Straits planter, remarks on the curing question: "What makes our bean so unpopular with buyers in great measure is the adherence of the silver skin to the bean. Many of us think this can be overcome by subjecting the parchment to a high temperature artificially, thereby contracting the bean itself before the silver skin has time to adhere to it. Experiments made in this way have shown that the silver skin so much disliked comes off quite clean, and leaves the bean itself with a grand colour visible."

The London Market.

Coffee.—The demand has continued slow, says the *P. M. Review* of 19th March, and as the recent arrivals have been pressed forward the market has been dull, and a lower range of values has been established. The fall has also been accelerated by a further reduction in the terminal market, where heavy receipts and a decline in the rate of exchange to 6¼*d.* has brought prices down 9*d.* to 1*s.* per cwt. At auction some home trade sorts have sold well, and Mysore and other kinds of East India, of which there has been only a small supply for some time, have fetched full rates for the bold, while the other sizes have sold at about the recent values. Costa Rica and Guatemala, however, which are more ruled by the export demand, have given way considerably, and are now relatively much the cheapest descriptions offering. Plantation Ceylon has sold well, while there has been more demand for Mocha, and quotations, "cost and freight," are some shillings above those recently ruling.

Indian Teas.—Of the 27,643 packages brought forward at the public sales a considerable portion consisted of common qualities of both whole and broken leafs. As these latter grades meet with but a moderate demand, it is not surprising that values are irregular, and before the present large stock is materially reduced, holders must be prepared to accept a lower range of prices than is now current. Of the above quantity 3,210 packages were withdrawn from sale, mainly comprising undesirable sorts and Calcutta-bought teas, which have since met with little attention. There is no doubt that teas re-printed for public sale, as a rule, receive but scant attention, although, in a few cases, better rates may occasionally be obtained, but generally owners are less fortunate in their realisations than they would have been in accepting the

rices bid when first submitted to auction. This is easily nderstood, as the trade have quite enough tea to occupy neir attention without going to the trouble and expense f sampling and valuing two or three times over. Notvithstanding the moderate demand, the market remains rm for all grades removed from the very common and hin liquory descriptions, and therefore, with a more active nquiry, a higher range of prices is almost certain to take lace a little later on. There has lately been more inquiry or good medium kinds, particularly for Assam growths, nd these are the teas most likely to be influenced by an pward movement in values, as any addition to the stock y later arrivals will probably be very small, the majority f the gardens having disposed of the past season's roduction.

GENERAL ARTICLES.

THE U. P. A. S. I. SECTION.

The Ladybird Scheme.

THE following is the first narrative report of Mr. H. O. Newport, who has proceeded to Australia to collect ladybirds with a view to the extermination of scale pests :—

BRISBANE, *6th March* 1898.

DEAR SIR,

I arrived in Australia safely, landing from the *Oruba* at Sydney on the 19th February.

I stayed at the "Australia" Hotel while there, and proceeded at once to the shipping offices to make arrangements for the completion of my journey.

I learnt that the usual boat for Brisbane had left the harbour as the *Oruba* came in ; the next boat would sail in three days, but they could not book me a passage at once for various reasons.

On the next two days I went to the office about this, and was at last told that the whole boat had been chartered by an Operatic Company and no berths could be booked at all. They offered to book me a passage in a boat sailing in another four days, but rather than delay so long, I came on by rail, leaving Sydney on Friday and arriving here late on Saturday evening, the 26th February.

The Brisbane Post Office does not open on Sundays at all, and I was able to obtain no postal information. On Monday I learnt that the mails for India had left at 6 A.M. that morning. Hence my omission to report my arrival here by an earlier mail.

On Monday, the 28th February, I proceeded to the Secretariat and delivered my credentials to the Under Secretary to Government, the Chief Secretary being away.

Mr. Dutton received me cordially, saying that he had heard directly from the Madras Government the mail before and was expecting me. He referred me to the Agricultural Department, making an appointment for me to meet the Minister for Agriculture the next morning and also to see the Premier.

The Premier—Sir Hugh Nelson, whom I interviewed the following day—said much the same, adding that the Government would assist me in any way they could, and he would give me free Government passes over the Railways, should it be found necessary for me to travel.

The Minister of Agriculture introduced me at once to Mr. Henry Tryon, the Government Entomologist, and I proceeded at once to his office and had a long interview with him.

I naturally questioned Mr. Tryon regarding the telegram that was sent to him by the Acting Secretary, U. P. A. S. I., but to which no reply had been received before I left India. He said that not knowing the telegraphic reply had been prepaid, he had mailed a reply. In this reply he had suggested that the person sent out should wait till after the Colonial winter, anticipating a delay of six or eight weeks at least before anything would be done by the U. P. A. On seeing me, he said, however, that he was glad I had come out now; that I was in good time for the autumnal brood of ladybirds which would last for another two months or so. That, moreover, I could get back to India at a good time of year, and save nearly a year in time.

Mr. Tryon said he would write by this mail to the U. P. A. S. I. corroborating what I have just said.

I have naturally not been able to get into full swing of work immediately on arrival. Indeed, Mr. Tryon advises my not collecting in quantity yet awhile, nor should I have been able to do so if I had wished to, for want of knowledge with regard to identification and of apparatus.

The necessary apparatus is not much, and I have now obtained nearly all through the kindness of Mr. Tryon.

I have found my time during the first week fully occupied, however, with interviewing many gentlemen, and going about to various estates, seeing scale pests and ladybirds, with letters of introduction from the Ministers of the various Departments, or Mr. Tryon himself.

At present my work consists in collecting dead specimens of ladybirds, etc., under the supervision of Mr. Tryon, and mounting them —taking notes and making observations meanwhile of localities and habits—for subsequent identification.

This work, as you will understand, is very important and necessary, for there are a vast number of coccinellidæ that are harmful, as well as those that are useful in destroying various scale pests.

I have already been out in some three or four directions by rail, and on foot to places where Professor Koebele went on his last visit here ; but for the present the indoor work—microscopic examination and observation of structural differences between specimens (some are very minute)—occupies as much, if not more, time than the actual collection.

Mr. Tryon thinks that the investigation and subsequent work will take some two or three months in Australia, and be hard work then.

At present I am still at an hotel, but as it has been suggested that I had better make Brisbane my headquarters, returning here from my tours into the country, I propose getting rooms somewhere near the offices, which will not only be more convenient, giving me more room and quiet for my indoor work, but will also be more economical.

So far as I can see now, the allowance on the estimate for the expenses of bringing to India the consignments of ladybirds will have to be somewhat increased.

The refrigerators on the ordinary liners vary considerably in temperature, I understand, and are frequently below freezing point, while the consignments I bring out will have to be kept at a uniform temperature some degrees above freezing. This may necessitate my having a special ice case made, which may cost a few pounds, and also occupy more room on boardship.

I do not anticipate having to draw more funds, however, and think the funds I have in hand will be ample to cover all expenses, provided the investigation does not extend over the three months estimated, the more especially if I can retrench in the matter of travelling expenses by having free Government passes on all Railways.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

Advertisers are notified to send all advertisement matter and answers to advertisements direct to Manager, this paper, 11 and 12, Second Line Beach, Madras.

Correspondence and matter for publication to be sent to Editor, this paper, Coonoor.

I am very glad to report that so far the work is progressing satisfactorily, and I have every reason to think I shall be able to work the scheme to a most successful issue.

With regard to shipments of ladybirds and arrangements for their reception, I will write fully by a later mail.

I am, Sir,
Yours faithfully,
(Signed) HOWARD NEWPORT.

TEA IN ENGLAND.

The annual reports of the leading London Tea Brokers have always a special interest for the planting community in India, for they contain a critical and at the same time a friendly review of the year's business that deserves careful study. We have just received the report of Messrs. Geo. White and Co., dated 23rd ultimo. It is unnecessary to give it in full, as a great part relates to China, Ceylon and Java teas. A brief abstract will, however, interest our readers.

Messrs. Geo. White and Co. estimate that there will be about 3,000,000 lb. more Indian tea to be dealt with this season than there was last. They describe "quality from the different districts generally" as "not of an attractive character." Assams proved the best. Darjeelings were, on the whole, disappointing; Dooars were at times good, but the bulk was below that of 1896. Cachars and Sylhets were of ordinary style, while the produce of the North-West districts and that of the Madras Presidency was not up to that of former years. In short, Messrs. Geo. White and Co. refer to the feature of the season as "the superabundance of plains and characterless teas." This, naturally, caused a very low range of values to be established for these descriptions, while owners of fine full-flavoured parcels reaped a corresponding advantage. The reduced scale of values has not stimulated consumption. The labour troubles, and advertisements of Cocoa are referred to as probably explaining this. The Ceylon crop was fairly good in quality, while as regards Java "quality was fully maintained, and the style of manufacture for the most part was of a very useful description." The most natural inference from this is, that India must attend to the maintenance of her quality standards, and must also advertise her wares. The London Brokers referred to certainly anticipate an increased demand, and their report conveys the impression that stocks in England are of a very healthy size. No difficulty in distributing the increased yield of British-grown tea is anticipated. But the diminution that has been constantly occurring in the supplies from China cannot go on for ever, and, once again, Messrs. White hammer an old nail on the head, saying:—"It is necessary that every endeavour should be made to further foster other markets." Once again, too, the question is raised, "If the local consumption in the East Indies among the teeming native populations could also be encouraged." It is rightly observed that if this could be done, a large quantity of coarse leaf and dust might be worked off which at present often does not realise sufficient to cover cost and freight to this country, and tends to increase the supply of poor and low class grades which are really not wanted." It is even observed that "the interests of growers would be much benefited if a mutual movement in this direction could be made by some influential associations, which might be subsidised, even if it was considered advisable to make a compulsory 'cess' for that purpose on each property."

Among other suggestions thrown out, the following are noticeable:—(1) "Instead of spending large sums of money on new clearances, it would often be advantageous to increase the labour force and concentrate attention on the cultivation and improvement of existing gardens." (2) A succession of small shipments at short intervals from one estate is inadvisable, as often also the sorting into too many grades. "A Broken Pekoe of, say, 30 chests or more; a good Pekoe of 50 chests or over; a Pekoe Souchong of 70 chests or upwards, with a break o Broken Tea or Pekoe Fannings will generally be found t answer." (3) Dust should be sifted out and packed by itself.

Our readers will no doubt be interested in the above remarks which show that London brokers are anxious to see India teas gaining ground. Tea in this Presidency is but a smal thing at present, but it is developing, and if South India planters take useful hints when given, and are quick to adop improvements of manufacture, or packing, or selection, the may reasonably hope to see demand for their teas increase They will certainly be interested in reading the following remarks, which Messrs. Geo. White and Co. give under th heading:—

Analysis of Crop from India.

Assam.—The yield from this district has, on the whole, beer above the average, many of the shipments being of a very desir able character, whilst the leaf of those possessing autumn flavou was in most cases devoid of the reddish appearance which often depreciates the value of closing invoices. Owing to the scarcity of good liquoring parcels from other quarters, the Trade was anxious to secure these at enhanced prices. Output for 189 was barely up to that of the previous year, being 58 million lbs against $59\frac{1}{2}$ million lbs. in 1896, and compares with $55\frac{1}{2}$ million lbs. in 1895.

Cachar and Sylhet.—As a rule the crop was below par i cup, but the teas were well made and of a saleable description The total manufacture was rather more, viz., $46\frac{1}{4}$ million lbs opposed to $45\frac{1}{2}$ million lbs. and $39\frac{3}{4}$ million lbs. in the two pre ceding seasons.

Darjeeling and Terai.—With few exceptions quality was decidedly inferior and averages disappointing almost through out, weather having been very unpropitious for the production of fine flavour. For three seasons, 11, $11\frac{1}{2}$ and $10\frac{3}{4}$ million lbs were sent away.

Dooars.—Although receipts were of a fairly useful character throughout, there was a lack of invoices with full coloury infu sions similar to those of 1896. On account of the increased acreage coming into bearing, nearly 24 million lbs. were des patched from the gardens, contrasted with 22 and 20 million lbs in the two years before.

Chittagong. There is nothing special to note in the outturn from here the yield being about the same as last year, viz. 1,000,000, as against 800,000 lbs. in 1895.

Kangra, Dera Doon and Kumaon.—Weather appears to have been unfavourable all through the season for making the fine quality for which the former district was noted, while the crop from the last two continues to be principally disposed of locally. The quantity manufactured was similar to that for the last two years, namely, about four million lbs.

Travancore and S. India—From the Madras Presidency a few nice flavoured teas have been received, especially from among those grown on the Neilgherry Hills and the Wynaad

Apply "Observer Office,"
Colombo.

The larger amount, however, has come from Travancore, which, though of useful style with few exceptions, did not show the strong dark liquors which at one time were a leading feature of these teas. About 3 million lbs. have been shipped to this country against $2\frac{3}{4}$ and $2\frac{1}{2}$ million lbs. in 1896 and 1895 respectively.

POTASH AND ITS FUNCTIONS IN AGRICULTURE.

The following is a brief summary of an exhaustive paper on the above subject, by the Chief of the Division of Chemistry in the United States Department of Agriculture:—

1. The potash used in fertilizers and found in the soil has been derived from the decay of minerals containing it as an ingredient, and chiefly from feldspars.

2. During the progress of weathering, a portion of the potash in original rocks becomes soluble and is lost by lixiviation. As a rule, about 25 per cent. of the potash finds its way by this means into the streams and seas.

3. There is usually a less percentage of potash in the finer particles of soil than in the coarser particles, and this is due to the fact that the solvent action of water is more strongly exerted upon the finer particles.

4. The potash is quite evenly distributed, both in the soil and subsoil, there being only a slightly greater proportion in the deeper layers, doubtless to the fact that they have not been so thoroughly leached.

5. The solubility of potash in the soil is very different for different solvents, the least for the weak organic acids, and greatest for the strong mineral acids. Hot hydrochloric acid extracts from the soil about 20 per cent. of its total potash contents, which is about thirty-two times as much as is removed by a 1 per cent. citric acid solution.

6. A fertile virgin soil contains about 2 per cent. of total potash, or about 70,000 pounds per acre taken to the depth of one foot. A crop removing 50 pounds of potash a year could be grown consecutively for about one thousand four hundred years on such a soil before exhausting all the potash which it contains.

7. The soil retains a certain quantity of fertilizing material with such tenacity as to render it practically impossible for plants to withdraw the whole of it, thus protecting the future against the rapacity of the present.

8. The quantity of potash removed by various crops per annum varies greatly. The largest quantities are removed by beets, and the smallest quantities by cereals and cotton. Beets may remove as much as 100 pounds per acre, cereals about 30 pounds, and cotton about 23 pounds for the average crops as produced in this country. In Germany, beets grown for forage remove often over 200 pounds of potash per acre from the soil, clover hay about 74 pounds and tobacco the same quantity.

9. Tobacco contains a larger proportion of potash than any other common crop, *viz.*, about 40 parts per thousand of the dry leaves. Forage beets contain 35, potatoes 20, sugar beets 18, clover hay 19, beans 13, and cereals 5 parts per thousand.

10. There is about four times as much potash in the straw of cereals as in the grains, while in peas and beans the proportion is about as two to one.

11. A soil which yields about 0·01 per cent. of potash to a 1 per cent. citric acid solution, and contains about 0·30 per cent. soluble in hydrochloric acid, does not usually need a potash fertilizer.

12. The potash salts which supply the commercial potash fertilizers of the world have been deposited as the result of the evaporation of saline lakes charged with potassic materials.

13. The commercial potash of the world is derived almost exclusively from the neighbourhood of Stassfurt, in Germany. The quantity of crude salts annually mined is about three-quarters of a million tons, worth nearly three million dollars.

14. The high-grade commercial salts used for fertilizing purposes are manufactured from the crude salts, and are to be preferred when shipments are made to great distances and at high rates of freight.

15. The principal crude potash salts used for fertilizing purposes are kainite containing 12·5 per cent. of potash, and carnallite containing 9·9 per cent.

16. Tobacco waste, cotton seed hulls, and wood ashes also furnish important quantities of potash for fertilizing purposes.

17. Recovered marsh or swamp lands and lands containing large quantities of sand need, almost universally, a potash fertilizer. The percentage of potash in soils usually rises with their contents of clay.

18. The maximum effect from fertilization with potash is secured only when other plant foods are supplied in such a way as to make a well-balanced ratio, and where proper methods of culture are employed.

19. Lime is an important adjunct to potash fertilization, and, as a rule, should be added to a soil in large quantities wherever potash is applied.

20. The best kind of potash fertilizer is determined by local conditions, freights and the nature of the soil and the crop. Fertilizers containing considerable quantities of chlorine should never be applied to vineyards and tobacco fields.

21. In intensive pot or garden culture, where highly-concentrated plant foods are desired and where the cost of the fertilizer is unimportant, potash may be applied in the form of phosphate or nitrate.

22. In some soil potash salts, in common with other saline bodies, produce injurious effects by reason of their hygroscopic nature, attracting moisture, and, on drying, producing a cementation of the soil, which renders it impervious to water and impenetrable by the rootlets of plants.

23. Crude potash salts can be applied with benefit in the preservation of stall manure, but their value for this purpose is perhaps over-estimated.

24. Potash fertilizers should, as a rule, be applied in the autumn, or at least from two to four weeks before planting, and should be thoroughly worked into the deeper part of the soil in order to come into contact with the rootlets of the plant.

25. The germination of seeds, especially if they have a low vitality, is retarded by bringing them into direct contact with potash salts.

26. The application of crude potash salts to a soil which is not easily cemented may be useful during a dry season by reason of their power of attracting and holding moisture.

27. Potash salts favor the decomposition of mineral particles in the soil, and thus tend to add to the stores of plant food therein.

28. The application of crude potash salts to the soil tends to protect the crop from frosts by preventing the too rapid evaporation of moisture and by producing a more luxuriant foliage.

29. The too abundant application of potash to the soil may become injurious by reason of the retardation of the process of nitrification which it produces.

30. Crude potash salts, especially kainite, when added abundantly to a soil, are said to act, to a certain extent, as an insecticide or a preventive of disease, and when mixed with stable manure act as a preservative by checking the activity of the denitrifying ferments.

31. It is impracticable to give formulas for the preparation of fertilizers containing potash, since both the quantity of potash to by used and the form in which it should be applied are determined be local conditions, which cannot be taken into account in the preparation of directions for the use of fertilizers.

LIBERIAN IN THE STRAITS.

(*Continued from page* 150.)

Estimates. In the foregoing chapters I have endeavoured to impart all I know about "Coffee Planting" from the moment the seed is sown until the coffee is ready for sale, and I might now make a bow and say: "Ladies and Gentlemen, if I have succeeded in interesting you in a form of

THE MADRAS SALES AND AGENCY COMPANY, (Ld.)

cultivation upon which the future of Malaya so greatly depends, I am amply repaid for the time and care I have devoted to these notes," but I feel that they would not be complete without an estimate.

In planting, as in most things in life, the prosaic and practical cash question figures largely, and people, however much they may be interested or amused, naturally like to know about the prospects of gain, or loss, by the venture.

I would have preferred to avoid this subject. Estimates are the most unreliable things in the world—one man will spend a hundred dollars where another would only spend thirty-five. One particular piece of good soil well looked after will give you a return of 10 to 12 pikuls per acre, whilst another will only give you one or two. And then there comes the price: if I estimate $40 a pikul when the price is $50 in the market, by the time the coffee is in bearing it will probably be down to $25.* However, I will give, to the best of my ability and knowledge, a safe and fair average estimate:—

Estimate for opening and bringing into bearing 100 *acres of Liberian Coffee.*

Average expenditure $80 per acre per year, including everything —buildings, machinery, supervision, manure, quit-rent, etc.

Crop one pikul per acre the 4th year of opening
three „ 5th „
five „ 6th „ and following years.

	1st year.	2nd year.	3rd year.	4th year.	5th year.	6th year.
Expenditure	$8,000	$8,000	$8,000	$8,000	$8,000	$8,000
Crop in pikul	...	...	...	100	300	500
Value of crop in $	...	...	...	$4,000	$12,000	$20,000
Surplus of—						
Expenditure	$8,000	$8,000	$8,000	$4,000		
Revenue	...	...	...	...	$4,000	$12,000

From the above it will be seen that I estimate a capital of about $30,000 to open an estate of 100 acres of Liberian coffee and on getting about 40 to 50 % per annum after five years on the invested capital.

Book-keeping and accounts. It is not sufficient that a planter should himself be satisfied that he has spent his money in the most economical way, he should also be able to show by his books and accounts, at any moment, what he has spent and how he has spent it; and how much he has paid an acre for weeding or felling, how much for picking per box, what his expenses were for curing a pikul, and so on. Each planter keeps his books in his own particular style but, as a guidance to those who have not yet adopted a fixed system of their own, I just mention the books generally used amongst planters, they are:

1. Register of Coolies; 2 Check Roll; 3. Distribution of Labour; 4. Stock book; 5. Cash Book; 6. Ledger; 7. Monthly Report Book. Of each of these I will give a *pro formâ* page.

If all these books are properly kept I think it will enable the planter to show pretty clearly how he stands and what is the financial position of his estate. The great secret of success, mercantile or otherwise, is always to know how you stand: if you can see your own position clearly, you have won half the battle. Book-keeping is of very great importance: without it you would be working in the dark, not knowing whether you were working cheap or dear, and you might be hastening to ruin, while imagining yourself all the time as rich as Croesus.

It is the old story again, a fool never knows that he is a fool, because the moment he sees it he ceases to be one. That is so with book-keeping, too. You never see how fast you are going the wrong way until you keep books, but when you do keep them you can see clearly enough and you pull up sharp.

Order, system, and a clear organisation of your books and accounts are the indispensable foundation of every great enterprise, and I think I may safely say that whatever little success I have scored in my life and whatever great calamities I have escaped, I owe it to my system of keeping my books and accounts in proper order and always up to date.

Treatment of coolies. Whether you plant coffee, tobacco, or anything else, you will never be successful unless you know how to treat your coolies and how to get on with them. It is just as essential for a young planter t know how to treat his coolies as it is for him to know how t treat his coffee trees. If the cultivation of the coffee tree is neglect ed we know very well what the consequence will be, but if th cultivation of your labour force is neglected, your knowledge an experience of planting, be it ever so great, will not save you fro failure. There are some planters who insist upon what they consi der their legal rights and drag the cooly into court and have hi locked up for every petty minor offence; others are too good an give in to the coolies in every case whether reasonable or otherwise others say, "Bother the court, I am my own court of justice," an they hammer and thrash their ideas of civilisation and good manner in and out of their coolies; others despise such rude treatment which they consider unworthy of a gentleman and a planter, an bring their coolies to reason by fining them 50 cents here and dollar there, and when the cooly receives his pay at the end of th month—or, rather, what's left of it—"that's where he feels it th most," as a popular song goes.

Some planters doctor their coolies themselves; all who are sic have to fall in, those to the right get a dose of quinine and those t the left a dose of castor oil. Others cure them with a rattan, and have seen some most wonderful cures effected with this patent medi cine, people half dead and paralysed turning summersaults which would have put the professional acrobat to shame. Then, again, have seen coolies who had scratched their little finger being carefull bandaged and nursed by the planter, fed on Liebig's extract of mea and port wine and carried about on a long chair. The proper treat ment will probably lie between these extremes. It is very difficul to say always what a planter should do; the best plan will be to give a few instances of my own experience with the treatment of coolies

I had contracted with some Malays to fell the jungle near som coffee in bearing. Through their own carelessness and fault they managed to drop a big tree right on the top of the coffee and smashe about sixty fine trees covered with berry; I cut them $5 for this and the morning after they left the estate about another 200 trees al around the same spot were found cut down. I offered a reward o $100 to catch the men; they were never caught or seen again. wish now I had not fined them $5, although I am still of opinion that they fully deserved it.

In another case a planter had been assaulted by his coolies. All hi coolies were striking and refused to go to work, the ringleaders were arrested, tried and sentenced to 14 days' imprisonment. When they came out of gaol they left the estate, the others all "gave notice" too and the planter lost them and had to get new men at great expens and inconvenience. What do you think was the origin and cause o all the row and trouble? The planter wanted to show his coolies hov much at heart he had their comfort, how much he wanted to mak them feel at home, and he therefore made a pretty flower garde in front of the cooly line; but the coolies did not appreciate hi good intention any more than they did the flower garden, ove which they walked, it being the shortest cut to the nearest well The planter grew wild at this, and gave orders that broken bottle should be strewn near and round about the path they had made acros the flower bed. One of the coolies in attempting to walk over it cu his foot, and wanted to stay at home on account of it; but the plant er insisted on his going out to work, which resulted in the cooly giving notice, whereupon the planter said you need not wait till th end of the month, you can go at once and he turned him out; the the other coolies said, "If he goes we go, and at once too." Whe the planter wanted to "go" for the most impertinent ones of the lot the whole crowd turned on him and gave him a good thrashing, with the result, as we have seen above, that the coolies were locked up Now I think this planter would have done much better and wiser b letting the coolies and their flower garden alone, although, I am sorry to say, that particular planter does not agree with me and is fully convinced up to this present day that he proved himself awfully smart and clever.

The third and last case which I wish to relate here is of a planter who had a very good overseer, a man who understood his work thoroughly and, which is quite an exception, kept the coolies under his thumb; he was really "bossing the show," and the planter had not to trouble himself about anything. But one fine day the coolies complained that this overseer was cheating and ill-treating them

* The local price for Liberian coffee is now only 19 dollars per pikul ($1\frac{1}{6}$ cent).— Ed., *P. O.*

and they therefore came to the planter for protection and justice; they looked up to him, as their master, to deal honestly with them and between them and their overseer. He had now to choose between them and the overseer if he remained they, the coolies, would all go. What was he to do? The overseer was a good man and he did not wish to lose him; but the coolies would not listen to reason; if the overseer didn't go they would, every man Jack of them, and quickly, too. He would not give in, he kept the overseer and lost his coolies. Of course he had the protection of the law and the coolies were punished; but he lost them, all the same.

"Well," said the planter to me, "you disapprove, although in my own mind I have no doubt that I did quite right. I would never have been master again on my own estate, if I had given in. Of course it is very easy to criticise and to find fault with anything other people may do; but tell me, if you are so clever, what would you have done in my case?"

"H'm," I said, "I really don't know what I would have done in your case; but I don't mind telling you what I think you should have done. When you saw that the coolies were determined to go, you should have dismissed the overseer.

"What? Dismissed a man who had been working honestly in my interests and to my entire satisfaction simply because the coolies wanted it?"

"Yes, you should have dismissed him; but you should have told him quietly to get other coolies, and as soon as he had obtained them you should have said that, after careful reconsideration of the case, you did not think it fair to let the overseer go and you had therefore called him back, and whoever did not like it, might leave. I don't think anyone would have gone then. Or, if you really could do without them, you should have told them, after you had the new coolies, that you had decided in favour of the overseer and that therefore you did not require their services any longer. They probably would have told you then that they wished to stay, or they might have accused you of mean and false play in not informing them of this at the time, when they complained and when they could have obtained another billet, and that it was very hard on them to be turned out at a moment's notice with no other place to go to. Then you could have retorted: 'Yes, I quite agree with you, it is very mean; but that's just what I want it to be. Had I told you of my intention at the time when you put the knife to my throat, you would all have gone and left me in a fearful fix. Did you think I was such an ass? You were the scoundrels who gave me the moment's notice, and you left no other choice open to me than either to let my plantation go to the dogs or apparently to give in to you. I chose the latter. Now we are quits; clear out, and let this be a lesson to you for the future."

And the moral of all these little stories? Learn how to treat your coolies, be fair to them and reasonable, but don't interfere with them more than is absolutely necessary.

It is also your duty to see that the men get proper medical treatment when they are sick, and for that reason there should be a dispensary on every estate, and every planter should have some knowledge of how to render first help and assistance in case of accidents; but on the other hand, if the cooly is not sick and simply does not feel inclined to work, don't force him; he loses his day's pay and his Sunday and you should be satisfied with this, and you may be sure he will not keep it up very long if you don't object.

Never by any means attempt to administer medicine to a native if he objects to it. If you try to relieve a man suffering from fever by giving him some quinine, and he objects to it and wishes to be treated by his own people, you may be quite sure, if he dies, they will put it down to your medicine and to your treatment, and if he recovers he will be fully convinced that he would have been on his legs long before, had it not been for your interference and beastly drugs.

Try and keep neutral in all rows and disputes: with a little tact and diplomacy you will easily be able to humour both parties; thus, in the first instance, never deal direct with your coolies, but always through their overseers, except when they wish to put a complaint before you. In that case, however much you may be convinced of their being entirely in the wrong and telling you a lot of lies, don't send them away, don't abuse them, but carefully and patiently listen to them and promise them to enquire into the matter and to see that they get justice; follow Government's example about the Straits Military Contribution, say that the case is having your most serious consideration and put them off until they get sick and tired of it. Follow the wise example of a well-known Governor, who once received a deputation of planters, who laid their grievances before him; he listened to them patiently, he sympathised with them, he even quite agreed with them that they had a grievance, but what could he do? He was not the Governor of *their* State; and then there was the Secretary of State, who would not sanction any such proposals as the planters wanted to have introduced, even if he, the Governor, would submit them; and then he really could only advise H.H. their Sultan and their Resident. That's the way to do it, never refuse and never commit yourself in any way—that's wisdom and policy.

Don't forget that we planters are not here to give Solomon's judgment and to dispense the wisdom of a Haroun Al Raschid; our object is to plant coffee and to make it pay, and to avoid any dispute with coolies as well as everybody else, as far as in our power to prevent it. If the people have a serious case let them fight it out between themselves, or let them take it before a magistrate, who is paid for it, and trained to listen to endless lies and stupifying nonsense, and probably enjoys it; but especially never interfere between husband and wife, even if he gives her a good thrashing; let him, she likes it; if you interfere, she will take her husband's part and both will go for you.

If you are in a rage about a cooly or a kangany, don't dismiss the man in a hurry; always remember that nothing is easier than to turn a good man out on the spur of the moment, but it is very difficult to get other and better men to fill their places. Be careful, therefore, think twice over it, and then sleep on it for a few nights, before you finally decide to dismiss a man.

No more honourable testimonials can be given to the planter than the planter can give himself by being able to point to coolies and servants of his who have been with him for many years; this shows at once that the planter is a reasonable and good master and from that it may be judged that he is also a good and careful planter.

Don't always insist on your rights. If a cooly wants to go and you can spare him, let him go and don't throw any obstacles in his way; that's narrow-minded. Give him every assistance and help, even let him go without long notice, if you see that he is really bent on going. And if he wishes to come back, don't refuse him, because he had left you before: he has since been with other masters and he comes back to you because he has found out the difference, and it is no use cutting off your nose to spite your face. That man will be a better cooly to you than he ever was before—until he again wants a change. The easier you make it for your coolies to leave your service, the easier it will be for you to get others. A quiet dignified manner will always impress an Asiatic, and the less excited you are the easier you will be able to settle their disputes and troubles. You may be able to knock a man down, that is only a question of animal strength; but you will never be able to make the men look up to you with respect because you happen to be so much stronger: they may fear you and hate you but that is all. A sensible man and a good planter guides his coolies with his brains and not with his fists.

(*To be continued.*)

LIGHT RAILWAYS.

Below we give extracts from the report of the Chief Engineer for Railways in Queensland who recently visited America and Europe and has embodied his observations in a paper laid before the Colonial Parliament:—

Some misconception appears, I think, to exist as to what really constitutes a light railway, and the conditions which affect the cost of construction. It may not, therefore, be deemed out of place if I offer a few preliminary remarks in connection therewith, before describing in detail the various railways of that class which I had the opportunity of inspecting, and of which I gathered some particulars in the countries I visited.

The term "light railway" is, of course, merely a comparative one. The Queensland railways are, for instance, of lighter construction generally and adapted to lower speeds than those of the wider gauge in New South Wales and Victoria, whilst the portable railways 2ft. gauge, used in developing and working sugar plantations in this colony and elsewhere are of still lighter construction, and carry much lighter rolling stock than our standard lines.

A light railway may properly be described as one which, in its essential features, is a departure from the standard or normal railways of the country, either as regards the gauge or character of the works, with a view to ensure economy of construction.

The primary conditions which determine the class of railway and cost of construction are as follow:—

(*a*) The Axle-load.—This is the most important factor in railway

onstruction as it decides the weight of rail, which should be duly roportioned to the load it has to support, the bearing surface, or, in ther words, the size and spacing of sleepers, the quality of ballast o be provided, and the strength of bridges and other structures.

(*b*) The Speed.—This has also a material influence on the chaacter of the permanent way, whilst it also affects, to some extent, he strength and solidity of the works, and determines the descripion of rolling stock.

(*c*) The Gauge.—Of itself this has a far less effect on the quesion of cost than is, I think, generally supposed; for unless the xleload and speed are also reduced the saving due merely to a arrower gauge resolves itself into a rather insignificant decrease in he quantity of earthwork and ballast, with somewhat shorter leepers, culverts, and drains.

(*d*) The Nature of traffic.—This will determine the extent of uildings and other works required for its proper accommodation, as ell as for the protection and repair of the rolling stock.

Besides those just mentioned, local conditions have frequently an mportant influence on the cost of construction, and must not be lost ight of in comparing the relative cost of railways, such as—

(1) The natural features of the country, and its geological ormation.

(2) The facilities offered for the supply of constructive material; nd

(3) The price of labor.

It is not uncommon to hear comparisons drawn between the cost f railways in one country with those in another, or even in different listricts of the same country, where these conditions are widely dis-imilar, and where, possibly, with much the same amount of work to e executed, the cost of constructiou is unavoidably greater in one ase than the other.

In approaching the important question of how to extend the dvantages of railway communication to sparsely populated districts, he prospective traffic from which cannot reasonably be expected to ive a fair return for the outlay involved in the construction of our rdinary standard lines, it becomes necessary to consider the best neans by which the desired end can be accomplished in the most economical manner consistent with efficiency as well as requisite apacity.

The cost of construction may be reduced in one of two ways:—

(*a*) By retaining the standard gauge, but employing lighter olling stock and a less expensive class of permanent way; or,

(*b*) By adopting a narrower gauge, with light rolling stock and works duly proportioned thereto.

The first expedient would appear to hold out special advantages in connection with extensions of main lines or branches which may be expected to develop into important parts of the trunk system, By employing locomotives with no greater axle-load than that of the ordinary goods waggons, the rolling stock from the main line could be utilised in working the traffic. If also the speed were reduced a lighter rail with less ballast might be provided, but as there would always be the tendency to resort to the use of heavier locomotives to meet the exigencies of traffic, it would not, I am of opinion, be advisable to alter the design of the bridges or other substructures. If circumstances warrant it, a heavier rail and more ballast can easily be laid, but the strengthening of bridges and other works on lines in operation is always attended with more or less difficulty and expense.

The average cost of permanent way, including rails and fastenings, sleeper and ballast, in this colony may be taken as follows:—

First class—60lb. rails and 1,760 cubic yards ballast, £1,540 per mile.

Second class—41¼lb. rails and 1,100 cubic yards ballast, £1,135 per mile.

With a 30lb. rail, which would be capable of sustaining an axle-load of, say, 5 tons, equal to that of our ordinary goods stock, and 880 cubic yards of ballast per mile, the cost would be reduced to £934 per mile, a saving of £200 per mile as compared with our second-class lines.

Unless, however, under exceptional circumstances, I should not recommend the use of rails of less weight than 41¼lb. on lines of standard gauge: in fact, on economic grounds I would much prefer that a 60lb. rail should be fixed as the minimum weight, at any rate for all main lines and principal branches.

I have not suggested resorting to steeper gradients than are now usual, as experience has, I think, conclusively shown that this is not a direction in which it is wise to economise; for whatever saving is effected in first cost is more than counterbalanced by the increased expense in the future working of the traffic.

Coming now to the alternative proposal of a reduction in gauge, it must be clearly understood that while I am fully alive to the advantages of uniformity in gauge, and should not, under any circumstances, recommend a departure from the existing standard as regards extensions of our main system, I think adherence to the principle may be carried too far, and that, under certain conditions a departure therefrom would not only be expedient, but justifiable.

There are many districts in the colony, more or less isolated, which are a great disadvantage through the absence of economical means of transit for produce to market, but where the probable traffic would not warrant the outlay on lines of normal construction. It is most desirable, with a view to relieve the wants of present as well as to encourage further settlement in such districts, that railway facilities should be extended to them; and if this object can be attained by means of light narrow-gauge lines, I should not hesitate to recommend their construction.

As regards the particular gauge which should be selected in such cases, I have found it generally conceded by those who have had experience in the construction and working of narrow-gauge railways, that, unless for special purposes, it is not advisable to employ a less gauge than 2ft. 6in., and in the event of its being decided to depart from our present standard, this is the gauge I should recommend to be adopted.

Where a light traffic has to be provided for, a narrow-gauge railway offers the following advantages:—

1. Reduction in Cost of Construction.—In flat or easy country the saving due to reduction in gauge is comparatively slight, but where rough country is met with the saving may become considerable, as the narrow gauge line, by admitting of the use of sharper curves, lends itself more readily to the natural features thus avoiding excessive earthwork and lessening the extent of bridgework, culverts and other substructures. I estimate the approximate relative cost between a railway of 3ft. 6in. and 2ft. 6in. gauge in flat country with ordinary provision for waterways and small stations at intervals of, say, five miles apart, but without large bridges or fencing and where constructive material is fairly plentiful, to be as under:—

Railway of 3ft. 6in. gauge, with 41¼lb. rails, £1,800 per mile.

Railway of 2ft. 6in. gauge, with 30lb. rails, £1,375 per mile.

Thus showing a minimum saving in favor of the latter of £425 per mile. In this estimate the cost of permanent way for the 2ft. 6in. gauge, with 30lb. rails and 800 cubic yards of ballast, is taken at £805 per mile, or a reduction of £330 per mile as compared with that of a second-class road on the 3ft. 6in. gauge. It is impossible to give definite estimates without having reliable data based upon actual survey in each case. Speaking generally, however, I should say that in moderate country, presenting no special obstacles to be overcome, the saving effected by the narrow gauge would probably range from £600 to £1,000 per mile, but where broken or mountainous country has to be traversed, the difference in favor of the narrow gauge might be considerably greater. In the above estimates I have assumed that the usual quantity of ballast will be provided. Even should it be found expedient in some cases to use a less quantity in the first instance, it would, I consider, be necessary in order to ensure economical maintenance, to supplement it afterwards; and provision should therefore be made for the additional expenditure from capital account.

2. Lighter, and consequently less costly, rolling stock, as well as a more favourable proportion between paying and dead load. With our present goods waggons the proportion of tare weight to carrying capacity is, on an average, about 7 to 13, but with light stock suited to a 2ft. 6in. gauge there is no difficulty in obtaining a ratio of 1 to 3. Thus, in a train of, say, 150 tons, consisting of goods waggons and break-van of our present standard stock, the maximum paying load would amount to 60 per cent., whilst with the narrow gauge light stock the paying load would be as much as 70 per cent. of the gross weight. This would represent a substantial saving in working expenses, and should enable goods to be carried at lower rates than is practicable with the wider gauge.

3. The lower speed for which the light narrow-gauge line is only adapted, would obviate the necessity of level crossings, gates, and signals, and in many instances fencing might be dispensed with. The public roads may also be availed of where the gradients are suitable, so as to avoid the resumption of land and payment of heavy claims for compensation.

4. The narrow-gauge railway, with its light rolling-stock and low

speeds, would cost less to maintain than a line with heavier stock in it at higher speeds.

5. The light railway being of less than the formal gauge, would effectually prevent the heavy stock of the main line being used upon it.

If the same gauge were adhered to there would always be the temptation to employ the heavier engine from the main line to cope with the exigencies of the traffic, thus increasing the cost of maintenance if not damaging the permanent way and works.

On the other hand, the undoubted drawbacks incidental to a break of gauge, and the adoption of a different class of railway to that now in operation must not be lost sight of, and should have due weight in considering the merits and financial aspect of each particular case. The chief objections appear to be the following:—

(1) The cost of transhipment of goods at the points of junction with the main line, as well as, in a minor degree, the inconvenience to passengers.

(2) The necessity of providing special equipment to work such lines, which must be sufficient to meet the demands of the maximum traffic. During slack seasons, therefore, a portion of the rolling-stock would lie idle, as it could not be utilised on the main line or conveniently transferred to other narrow-gauge lines.

As regards the first of these objections, I ascertained that the cost of transhipping goods in Europe varies from $2\frac{1}{2}d.$ to $4d.$ per ton, but as the rates of labour here are nearly 100 per cent. higher this item of expense cannot be estimated at less on an average than, say, $6d.$ per ton.

Before deciding to construct any branch line on a narrow-gauge the expense of transhipping should receive due consideration, and an estimate be prepared on the probable tonnage of goods. If it can be shown that the annual expense of transhipment would exceed or even equal the amount of interest on the additional capital required to construct a line on the standard gauge, it would be a question for consideration whether under these circumstances it would not be wiser to incur the increased outlay for the wider gauge in the first instance, than submit to perpetual charge against working expenses as the result of a break of gauge.

Various attempts have been made from time to time to minimise the inconvenience and expense of transhipment by the use of special appliances, such as the transfer of the bodies of trucks from one underframe to another, but none have proved altogether satisfactory, and so far as I observed, are only used in dealing with particular description of goods where it is important to avoid handling as much as possible. Experience seems to indicate that the least expensive and most expeditious method of overcoming the difficulty is by manual labour, suitable platforms, of course, being provided between the wide and narrow-gauge lines of rails for the purpose. For the transhipment of machinery and other heavy articles over head, gantries or travellers are usually employed, and transportation cars or "rolling cradles" are also, in some instances, made use of to convey the narrow-gauge waggons over the wider line and *vice versâ*. The latter expedient, although hardly suitable for the requirements of general traffic, is useful when it becomes necessary to send the narrow-gauge stock to the central workshops for repair, so as to avoid the expense of erecting special buildings for the purpose in connection with the narrow-gauge lines.

Mr. Stanley proceeds to give some particulars of the light railways which came under his observation during his recent travels, and adds the following

CONCLUSIONS AND RECOMMENDATIONS.

The light railways on the Continent, more especially those in Belgium, are generally admitted to have proved successful in attaining the object with which they were originally constructed—namely, to aid in the development of agricultural, industrial, and commercial pursuits, and have given, moreover, in many instances, apart from the indirect benefits accruing, a fair return of interest on the capital invested.

Their success is, I think, in a large measure to be attributed to the adoption of light rolling stock, combined with low speeds, to the simple character of the station arrangements, the absence of expensive accessories in the way of signals, and to the fact that, as far as practicable, the public highways are utilised so as to avoid the purchase of land. Although light sections are frequently used, the rails are, as a rule, somewhat heavier than is strictly necessary for the weight to be supported, but this departure is no doubt a wise one, as tending to economy in future maintenance.

As regards the practice of constructing these railways along the public roads, as generally followed on the continent, I am aware that the experiments made in that direction in this colony have not been received with much public favour. This, I think, has been due to the mistake of utilising the roads for the purpose of the ordinary type of railways, instead of adapting the class of railway to the conditions pertaining to road traffic. I feel satisfied that if light railways of similar character to those I saw on the Continent were constructed here, and low speeds insisted upon very little if any exception would be taken to their being run alongside the public roads.

The question of uniformity in gauge as affecting these secondary railways is not, I consider, one of much importance, except as regards such lines as there is reasonable prospect may be connected at some future time. But it is essential that whatever gauge be decided upon should be such as is adapted to the class of traffic to be served and afford the requisite carrying capacity.

The majority of these "district railways," as I think they might appropriately be named, will either be isolated lines or feeders to the main lines, more or less remote from each other, and there is not likely to be much opportunity of interchanging stock. It would, however, be convenient to adhere to one gauge as far as circumstances permit, so as to avoid multiplying the types of vehicles in use.

Whilst it is a fact that railways on a 2ft. gauge are being successfully worked in different parts of the world, and are well suited to certain kind of traffic, especially in mining districts, where the materials to be carried are heavy rather than bulky, I would advocate in preference the adoption of a gauge 2ft. 6in. as better adapted to purposes of general traffic, affording greater comfort to passengers, and larger carrying capacity in proportion to the capital cost. The rolling stock for this gauge can be constructed of nearly the same width as our present standard, and at the reduced speed for which it is adapted is perfectly stable and safe.

Keeping in view the conditions which, as already-pointed out, should determine the adoption of narrow gauge light railways instead of adhering to our existing type, I would recommend:—

(1) That one or more suitable districts should be selected in which to construct experimental railways on the 2ft. 6in. gauge.

(2) That special surveys be made for the purpose of preparing careful estimates, in order to ascertain in the saving to be effected as compared with the cost of a line on normal gauge.

(3) That, as the success of the experiment will largely depend upon the lines being properly equipped, the first supply, at any rate of rolling stock should be obtained from Europe, from manufacturers who make a speciality of its construction.

Respecting the substitution of electric for steam traction (a subject to which I have alluded as receiving attention at the present time from some of the leading railway managers in America), I think it is well worth consideration whether it might not be applied with advantage in connection with some of our suburban lines, where a frequent service of light trains would be likely to encourage passenger traffic, and enable the railway to compete on more equal terms with the tramways.

I would, therefore, suggest the desirableness of obtaining reliable estimates of the cost of providing the necessary power, laying down a third rail or cable as might be deemed best, and purchasing a suitable equipment of motor and other cars.—*The Sugar Journal.*

TWO BUCKETS AND A PIPE.

Take two common water-buckets; connect them at the bottom with a small pipe. Now undertake to fill one of them with water you perceive at once that the water tends to fill the other pail also.

"What's the use of saying that?" you ask me. "Every fool knows that water in connected reservoirs will assume the same level. Quite so. Yet the wisest men on earth didn't know it once. If the ancient Romans had known it they wouldn't have gone to the trouble and expense of building their great aqueducts. Oh, dear! oh, dear! After a thing is pointed out what a lot of people are able to see it!

But to see it the *first* time? Ah! that takes eyes. To explain it the *first* time? Ah! that takes brains. The blood circulated through pipes in the human body thousands of years before anybody ever suspected it. Isn't that queer? Now, there is a matter——but let's have an example or two first, and the theory afterwards.

A father writes thus about his daughter: "During the summer of 1890 my daughter, Rebecca, got into a weak, languid way. He

ppetite was poor, and after eating she had so much pain at the hest and sides that she didn't know where to put herself. She also omplained of pain in the pit of the stomach, in the throat, and at he back of her neck. Cold, clammy sweats used to break out all over er. Her breathing became short and laboured, and at times she ould not even lie in bed on account of it. She consulted two hysicians, who prescribed for her without avail.

" This was her general condition until January, 1893, when she egan taking Mother Seigel's Curative Syrup. This preparation ertainly had a remarkable effect. One bottle alone greatly relieved er. She relished her food, and got stronger. By simply continuing use this medicine in three months she was completely cured. ince then she has been well as ever she was. My married aughter, who has suffered from indigestion for a long time, seeing hat this remedy had done for Rebecca, took it also, with the same ood results. Yours truly, (Signed) Bartholomew Bell, Grocer, &c., rompton, Northallerton, October 25th, 1893."

" All my life," writes a woman, " I have suffered more or less rom sickness and spasms. I always felt weak, tired, and languid, nd had no desire for company. I had a bad taste in the mouth, and requently felt sick and prostrate. I had no relish for food, and fter eating, had pain at the chest and side. Such was my manner f life for years. Two years ago my sister told me of Seigel's Syrup ; tried it, and even a few doses relieved me. I continued taking it, nd soon my appetite improved, and my food digested. Since that me I have felt quite a new being—*so light-hearted and strong.* What a pity for me that I didn't know of Seigel's Syrup years before. ut better late than never. Yours truly, (Signed) Mrs. Annie oodger, 20, Bardolph Street, Leicester, May 10th, 1893."

" From childhood," says another, " I have suffered from indiges- ion and sick headaches. I never felt as if I wanted food, and after ating I experienced the usual pains and distresses of the confirmed yspeptic. The attacks of sickness and headache were often no less han dreadful. So-called medicines and remedies were, at the best, nly temporarily useful. In January, 1892, a friend living at Iackney, told me of Seigel's Syrup. I used it, and it cured me. *never felt so well in my life as I do now.* (Signed) Miss L. White, 2, Barnsbury Road, Islington, London, April 20th, 1893."

Now, see. Evidence like the above (though much more impressive) roves that Mother Seigel's Syrup either cures or relieves almost very known complaint. Yet it never was (nor is it now) recom- ended for any disease except indigestion and dyspepsia. What is he inference? That nearly every knowu complaint is caused by ndigestion and dyspepsia—is, indeed, a symptom of it.

" But everybody belives that nowadays," you say. Not everybody, ut very many. The rest will bye-and-bye. Although the fact is ld as Adam, the *discovery* of it is new. Yet the principle will pre- ently be as obvious to all as it now is to few.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (March 25, 1898) says :— A slow market has been experienced at Public Sale this week and values n nearly every case were in buyer's favour.

About 6,300 bags East India were offered and met a slow demand at declining rates for all except the finest grades and favourite Home Trade narks which were fully maintained.

Central American kinds have been difficult to dispose of and prices nark a further fall of 3/- to 4/- except for fancy marks of Costa Rica vhich sold steadily.

Futures still continue to decline on the heavy Brazilian receipts and quotations have given way 6d since our last, but the market closes steady.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for he Week ending March 23rd, 1898, says :—Bank rate 3%. Bombay Exchange closes at 1s. $3\frac{2}{32}$d. Brazil Exchange $6\frac{5}{32}$d. Rupee paper $31\frac{1}{2}$% $62\frac{1}{4}$. Silver 26d. per oz.

The heavy supplies brought forward have again met with a poor demand, and have only been partly sold at a further decline of 1s to 2s per cwt. London cleaned Central American kinds are very difficult of sale at even a greater decline, whilst fine marks of East India and Costa Rica realize full value. Brazil markets are lower, owing to heavy receipts, good average Santos having been sold down to 25s 6d c. & f.

Daily receipts averaged 11,300 bags in Rio and 13,100 bags in Santos.

Futures have continued dull and quiet, and close 3d to 6d per cwt. lower, viz. :—Good average Santos in Havre, May delivery, fcs. 33.75, in Hamburg pf. 28, and No. 7 low ordinary Rio in New York $5.00.

To-day's London official quotations are :—

	March	May	July	Sept.	Dec., '98.	Mar., '99.

35,007 *pkgs.* INDIAN
19,839 ,, CEYLON
583 ,, JAVA
} Total 55,429 packages were offered in public auction this week.

Home Consumption during the past nine months shows a slight falling off as compared with the same period last season ; this in face of increasing imports, is unfortunate and more than ever emphasizes the necessity for fostering outside markets.

It is possible that the direct services now organised between India and Ceylon, and New York, will have a considerable influence upon the trade with North America, as a decided preference is given to Teas which are really of "direct import" and arrive straight from the country of production.

GORTON SHIRTING.

FINE Gorton Shirting, F. No. 4, in pieces of about 80 yards, at $4\frac{1}{2}$ annas a yard.

SUBSCRIPTION.—Advance Rates : Yearly, Fifteen Rupees ; Half-yearly, Eight Rupees ; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be : 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee ; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," Esplanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 11 and 12, Second Line Beach, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 29th April, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

S. E. Wynaad. DEVALA, 20*th April.*—*Weather.*—There was no rain and no change in the weather since my last report, except on the 17th, 18th and 19th we have had a few showers, which did no good to the district ; it is very hot. The spikes are crying out and beginning to fade. *Health.*—Dysentery, diarrhœa, fever, colic and sore-eyes are prevalent.

Coorg. POLLI BETTA, 20*th April.*—*Weather.*—Rain on Sunday and Monday last, the 17th and 18th instant, from 30 to 60 cents. *Crops.*—Rain has started spike, but more rain needed to insure good set. Not unlikely that the needed rain will come. There is an abundance of good spike on the trees. *Labour.*—Hot weather supplies only retained. Moplahs and Thiyas at 4 annas a day are over-running the country.

Nilgiris. COONOOR, 20*th April.*—*Weather.*—The weather so far has been shamming in a most shameful manner. Sound and fury to any extent, but of the needed rain but little. I got 37 cents on the 17th and 15 cents on the 18th, with extremely high and cold winds. Kotagiri and Kil-Kotagiri seem to have got all the rain so far. Rain is still badly needed all round. Badagas are still busy planting up their fields, and it is consequently almost impossible to get them for plantation work. 21*st April.*—Last night 3 inches 27 cents !

KULLAKAMBY, 21*st April.*—*Weather.*—The rain has at last come, and though only quarter of an inch has fallen, there is promise of more, as the clouds are gathering, and the weather cloudy for the last few days. *Crops.*—Good promise of a fair crop, if the rain is sufficiently abundant, though some blossom has been burnt off. *General Health.*—Some fever still continues, but the general health is improving. *Labour.*—Plentiful ; some of the lower estates will soon dismiss the majority of

their coolies till June; the higher ones are still picking some crop, and all are putting in manure. *Interesting Items.*—A local sportsman has rid the district of a tigress and two cubs. The proud father of this once happy family is reported to be still at large.

Nellakotta, 19*th April.*—*Weather.*—"Rain, rain everywhere, but not a drop for us." At least, not as much as we need; 12 cents fell here on 16th and 6 last night. Heavy rain on the plateau on Saturday, and showers every afternoon to N. and N. W., but they systematically miss this district. *Crops.*—Spike has not suffered to any appreciable extent, and rain would ensure a real good crop. But it must come quickly now to be of service, as the small showers we have had have started the spike. *Plant-diseases.*—Coffee looking remarkably well, and quite free from leaf-disease. *General Health.*—Colds and fever amongst coolies. Planters suffering from the effects of "tension," about as horrible a disease as there is. *Labour.*—Ample. *Interesting Items.*—The large railway scheme proposed by the Madras Government includes a branch line from Erode to Nanjangud. When will the latter be linked with Gudalur? At the Greek kalends probably.

NITREFYING EARTH AS MANURE.

A Revolution in Manuring.

The scale of progress in the art of supplying nitrogenous manures to crops has been, on the whole, extremely rapid in the last half-century. Perhaps the rapidity of motion has been more in the theoretical and experimental line than in the fields and farms of the country, though there is no doubt that a vast change is observable there, as well as in agricultural research stations and laboratories. In popular estimation the original and most natural nitrogenous manure is undoubtedly the droppings of animals, which so many still hold to be the king of all manures. As the supply grew short and yearly more expensive, guanos, nitrates, sulphate of ammonia, and oil-cakes of various descriptions attracted prominent notice. So widespread, indeed, was, and still is, the demand for these so-called artificial fertilizers, that many supplies have already been exhausted, while we are within measurable distance of the total exhaustion of all known deposits of guano and nitrate of soda. Sulphate of ammonia, which is a bye-product of coal gas, is threatened by the daily increasing use of such substitutes for gas as electricity, acetylene gas, petroleum gas and so forth. Oil-cakes of course remain, but the supply is limited, and in a short time, were the demand increased, prohibitive prices would rule.

At this stage, general attention was and now is still attracted to what have been truly called the Nitrogen factories of Nature. The most familiar of these is the wonderful process of nitrogen collection that takes place in the root nodules of leguminous, *i.e.*, pod-bearing, plants. This process, which has met with universal acceptance by scientists, is little understood out here, though the practice of using leguminous plants as a manure for other crops seems well nigh as old as agriculture itself. The ancient Romans were adepts in its use, while still older is the custom that obtains in some parts of Southern India and Ceylon. Opinion is a great deal divided as to the best methods of utilizing the immense assistance that legumes can render to the intelligent agriculturist.

The second, and perhaps an even more important, Nitrogen factory worked by Dame Nature is that which is located i the surface soil of every non-barren soil in the wide worl We refer to the work of the Nitrefying Bacteria, the late use of which has suggested these remarks.

The existence of these bacteria is probably known to a who possess the rudiments of agricultural knowledge, but has been reserved for late years to demonstrate their full an true significance in Nature's cycle. Briefly, these bacteri are minute organisms that convert, by feeding thereon, th insoluble humus and vegetable matter in the soil into nitrate which are readily absorbed by the roots of plants. Thei action may, in a popular way, be compared to that of catt who convert the scattered and otherwise useless herbage the fields and forests into the valuable cattle-manure.

The conditions that favour the development of ou useful little allies are, first of all, of course, the presence sufficient food in the shape of vegetable remains. certain temperature is needed also, likewise a requisit amount of moisture, and, above all, free access to air. I Europe these conditions are usually only found combined certain seasons of the year, to wit, in summer and earl autumn. In early spring and winter their animate lif is suspended, and it takes an appreciable time befor the results of their labours can be appreciated by the crop to whom they minister. As it is precisely in early sprin that nitrates are most required and are most conspicuou by their absence, most interesting trials have been made i Europe to help these bacteria in their work. Experiment were made in France in taking soil from the field in autumn when the bacteria would otherwise think of retiring t private and unconscious life, and keeping this soil through out the winter in a warm room. The addition of moisture and frequent stirring up of the soil, enabled the bacteria t continue uninterrupted their useful work of the formatio of nitrates throughout the winter. Chemical analysis this protected soil and soil left *in situ* in the field conclu sively proved the vast superiority in nitrates of the forme over the latter. But this was not enough. A practica demonstration was needed. For this purpose a certai number of experimental plots were set aside and planted.

One series was manured with cattle-dung, and in additio with 2 cwt. of nitrate of soda (containing 15 per cent. nitrogen) per acre. The other series received an equa quantity of cattle-dung and in addition 2 cwt. of nitrefyin earth per acre. This earth was simply natural soil take from the field in autumn and treated, as already describe during the winter. These experiments were first unde taken in 1896, repeated in 1897, and conducted independ ently at different places and with different crops. Mr. Bau of the Ceylon Manure Works, in bringing the results these experiments to public attention, quotes from a rece report of the French Minister of Agriculture:—

"During their growth the plants, which were thus differenti manured, showed no difference in appearance, and when the produc was taken from the fields it was found that in most instances better crop was obtained from the plots which had received this nitr fying earth than from those which had received the nitrate of sod To still further demonstrate the influence which this nitrefying eart had on vegetation, two plots were set aside and planted. One receive an application of 2 cwt. of nitrate of soda and the other of 2 cw of nitrefying earth without any other manure being added, nor ha the two plots been manured the previous year. The results aga justified expectations, for the crop from the field which had receiv the 2 cwt. of nitrefying earth exceeded by about 10 per cen the crop from the field which had received the 2 cwt. of nitrate

da (which latter was equal to an application of 5 cwt. of best ite castor cake per acre). This favourable action of the nitrefying rth is not to be attributed to the insignificant quantity of nitrates roduced into the soil, but to the intervention of the micro-organ-ns, which, being maintained in full activity during winter, con-ued their work of fixing the nitrogen from the atmosphere and of ndering it available for the plants."

These remarkable results are surely enough to command e earnest attention of planters. The guiding principle of e experiments is, it must be noted, to remove and store e bacteria-infested soil at the moment of their greatest tivity, and just before the commencement of a season ien they sink into a comatose state. Subsequently this soil which has been kept under most favourable conditions—ould be applied to the field at the end of the inclement riod and at a time when plants are mostly in lack of trates, etc., and the conditions for their formation are vourable. It is not difficult to suggest corresponding periments in India, but our conditions being so dissimilar, is hopeless to expect them to be fully successful without pert assistance.

In districts afflicted with a heavy South-West Monsoon, e soil should be removed before the rains burst—as cessive moisture is as bad as frost to the well-being of the cteria—and might be applied directly they cease. In her districts where the conditions vary, different seasons ould be chosen. For instance, in a cold frosty locality with orth-East rains, September or October would be a suit-le month to store the soil, while early in February or the ginning of March might be chosen for its application.

NOTES.

a prices and con-sumption.

Readers of our market reports will find scant encouragement in Gow, Wilson and Stanton's remarks the continued decrease in duty payments since Decem-r last, accompanied by as steady a fall in price. March, owever, has shown an improvement, we are glad to note, clearances at least.

advertisers.

"Of" complains to us very bitterly of the way in which some adver-sers decline to reply to communications sent them in nswer to their advertisements. He suggests that if the dvertiser is so shy of disclosing his personality (in which se we would advise him not to advertise at all), he might least answer by means of an unsigned and unaddressed C.

good hedge plant.

"A useful fence or hedge plant will be found in the Cœcelpina" (*Log Wood*) writes a correspondent. Planted close, it is a strong nce, since its thorns keep goats and cattle from coming ear it. Treated as the Kutch wood of Burma, boiled in pen iron pans, the log wood juice is extracted, so saving reatly in freight home, otherwise the fencing should be pped every three years, the sticks "barked" and shipped me. It is a commodity commanding a sale and good price. grows wild in the Deccan, Central Provinces and engal, also in Burma. In these days of short crops, it might be worth planting at least as hedges, occasionally bringing grist to the mill.

Coffee in Upper India.

Firms in Calcutta are gradually turning their attention to coffee, writes a subscriber, one having planted up nearly one hundred acres, since high exchange has so adversely affected the meagre profits of all the low-priced qualities of tea. Some fifty years ago there were 70 acres of coffee flourishing where the great cotton mills at Bowreah, opposite Budge Budge, are erected. Some fine native grown coffee, 17 feet high and 38 years old, grown under shade, in good heart, and for the past four years not a speck of leaf-disease has been seen. The proprietor—happy man—did not know what it was like till it was carefully described to him. Coffee is grown in a small way in Chota Nagpore.

Dietetic value of fruit.

A celebrated French physician, Dr. Dupoury, divides fruit into five classes, each of which possesses a special hygienic value—the acid, the sweet, the astringent, the oily, and the mealy. To the first, including cherries, strawberries, raspberries, gooseberries, peaches, apples, lemons and oranges, he accords great merit. Cherries, however, he prohibits entirely to those affected with neuralgia of the stomach. Strawberries and raspberries he recommends warmly to those of bilious, plethoric and gouty temperament, and denies them to those on whom diabetes is present or suspected. Of the sweet fruits, he considers that plums are of special hygienic value, and even a preventative in gout and articular rheumatism. To the grape he accords the very first place.

New products in Africa.

Central African planters, in view of the fall in the market, are turning their attention to the old, but always new, subject of "New Products." We are glad to observe that their organ, the *Central African Times*, does not recommend tea being taken up, unless by large and well-equipped companies. Certain it is that tea would never pay in the dry coffee zone, though in the rainy forest districts it might possibly hold its own. Natal experience, as far as its London prices go, is certainly not encouraging. Tobacco is brought forward as a likely product, were expert curers imported for the treatment of the leaf. It is a mistake, though, to imagine that tobacco-growing would not pay unless good *cover* leaf can be produced. India is a standing example to the contrary. All the "cover" leaf, except that for the coarse cheap cheroots, is imported from Java and Sumatra.

Weeds! Weeds! Weeds!

A writer to a recent number of that interesting journal, *Indian Gardening*, draws very forcible attention to the danger of continuing the present policy of introducing noxious weeds into the country under the guise of ornamental plants, and then allowing them to disperse unchecked throughout the length and breadth of the land. In a recent visit to Ootacamund, which he rightly considers to be the centre of one of the most important planting districts of South India, he was struck with horror at the way certain pestiferous weeds were encouraged. He instances the white Ageratum, a

giant species of Polygonum, and the Oxalis, amongst others, as being signal examples of what pests certain plants can become.

He suggests that the introduction of weeds should be made penal, and that the Ootacamund Municipality should be empowered to keep down all existing noxious weeds.

Bananas from Queensland.

Recently there has been an experimental shipment landed here of bananas from Queensland, says the *London Produce World*. These bananas were brought over just to ascertain if the thing could be done, and it is very satisfactory to learn from Mr. George Randall, the Government Agricultural Lecturer for the Colony, that the bananas arrived in really splendid condition. They had been quite two months in the cool chamber, and this is regarded as a triumph in its way. A bunch of the fruit was exhibited on the Queensland Government Stand at the late Dairy Show. While on this topic of the cool chamber, it would appear from inquiries that in general American pears are subjected to a temperature of from 38 to 40 degrees F. Mr. Burney also states that his investigations have led him to the conclusion that all fruit can be transported by sea best when it is cooled prior to actual shipment.—*Ex.*

Regulation of sales.

At a Committee Meeting of the Indian Tea Association, held on the 29th ultimo, approval was given to the following notice, which has been issued to the trade by the Tea Brokers' Association of London, with reference to public auctions of Indian tea: "For the better regulation of sales, Indian tea importers have agreed to adopt the following rules: (1) That Indian tea sales be held on Mondays and Thursdays during eight months of the year, and on Mondays only from the first Monday in April until the last Monday in July. (2) That the quantity limit for Mondays be from 25,000 to 30,000 packages regulated so as not to require the sale to be continued later than 4 P.M. (3) Any surplus unsold from Monday's sale shall be offered on Wednesdays, no catalogue to be printed for Wednesday. (4) Small breaks appertaining to the tea offered to be sold at the close of each day's sale.

The New Currency Commission.

We note with great pleasure that the Ceylon Government will do its utmost to procure the nomination of the well-known Ceylon planter, Mr. Christie, on the new Currency Commission about to sit in London. Mr. Christie had the honour to represent the producers' interests on the 1893 Commission, held to report upon the closing of the mints, and then did yeoman's service. In the report of the debate on the subject in the House on the 29th ultimo, it is noted that the Committee will probably meet after the Easter vacation. Sir Henry Fowler is to be President, we are glad to note. Lord George Hamilton, as wired out before, held out no hopes of opening the mints, but he looked forward rather to the consummation of the policy that led to it, *i.e.*, the fixing of the rupee at a stable exchange of 1*s.* 4*d.*

Planting in Hawaii: a warning.

As most of our readers are aware, the annexation of the Sandwich Islands by the United Sates is only a question of time, and will probably be accomplished the next year or so. In many things, perhaps, the San wich Islands will be gainers by the transfer of Gover ment, but to the coffee and sugar planter the change m be disastrous. One of the chief causes of the prosperity the planting industry there is the cheap Asiatic contra labour to be had. But if the Islands should be annex the supply of contract labour would be immediately st ped. Planters would have to employ free labour, and grad ally Asiatic labour would become scarcer. This, as American supporter of annexation observes, will undou edly result in a considerable rise in the price of labour, *e if the intense agitation against Asiatic labour now prevail in the United States should not be at once transplanted to Islands.* Naturally, the prospect of having the only suita labour supply withdrawn from him does a great deal discount the otherwise brilliant inducements held out to would-be planter.

Artificial fertilization.

The following paragraph on fertilization of the date palm will read with interest. We take it from the London *Groc* which paper, however, betrays a curious lack of even Boa School botany :—

"Grocers are accustomed to handle dates, and usually know a d when they see one; but probably few of them are aware that there in dates such a thing as sex! 'I have even been told,' writes Harry Johnston, in a remarkably interesting report to the Forei Office on Tunis, 'that some male date palms are considered m vigorous than others, and have quite a reputation as sires.' If t report were not an official publication related to such grave affa as Blue Books, the reader might think this a sample of what Arten Ward calls a 'goak,' but it is, of course, sober fact. There are m and female date palms, and they require the aid of man in breedi Arabs climb the male date palm when it is in blossom, bring do the great spathe with its strongly scented white inflorescence (n unlike the flowers of a grass), climb the stem of the female tree, a shake the pollen over her blossoms, or else hang up the bloss alongside; then they climb another tree, and so on, until all the fem trees in the plantation have been fertilised. It is not necessary do more than hang up one small piece of male blossom, so that entire blossom of one male palm may serve for a good many fem trees. The blossom of the male date palm, therefore, is sold in market places divided into small pieces, so that you can buy a pen worth which may be sufficient for the two or three female palms your garden. Thus we find 'sex problems' even in trees. T ancients who thought trees felt and spoke cannot have been so wrong after all. It is curious how far down in the scale of Natu the great sex distinction is carried."

Theoretical prejudice.

It is extraordinary how har lived prejudice sometimes is, a how wilfully blind some men are to the side of the que tion opposite to that which they hold. Take, for instan the "legume" shade cult *question.* Out of every ten m one meets, perhaps one has taken the trouble to go in the question, and is therefore a thorough believer in it. the remainder three are doubtful, but wish to try it, wh the other five loudly condemn it from their impart standpoint of delightful ignorance. The idea, they e claim, of a plant or tree being able to enrich the lan It's against Nature. Look at corn, coffee and other crop do these enrich the soil, do they not all require expensi manuring? If they appeal to Nature, to Nature they sh certainly go. Being doubtless of a logical turn of min they consider that forests impoverish the soil, and that

plant in such land is the height of folly. No, they object, we refer to a crop which is removed from the soil, not to forests. Well, are shade trees "cropped"? If not, they must tend to enrich the soil, whether they use part of the manure given to the plants they protect, or not. Yes, is the rejoinder, that may be all very well, but how do you make out that leguminous trees of a particular sort are better than other trees, or even other leguminous trees? The only answer to that, with the space at our disposal, is to refer them to the back numbers of this paper, where the ins and outs of the matter have been set forth exhaustively for their benefit, had they taken the trouble to read and digest the articles.

Cheap wire bridges. The usual style of wire bridge known in this country is rather an expensive affair, but the ones now in favour in Central Africa seem to be far simpler, just as strong, if not stronger, and a great deal cheaper. The way in which they are erected is as follows:—"The wire is got out in coils, and does not cost so much as one might expect. A couple of stout posts are put in about eight feet apart on each side, if possible at a place where the banks are high and steep. Holes are bored in these posts at the requisite height and the wire rope passed through from bank to bank. The wire is then secured, or anchored, at one end first by means of short posts driven firmly into the ground in a slanting position, and then the other end is pulled as tight as possible by means of a gang of natives and hauling gear, and when sufficiently taut is also anchored. This part of the work over, it only remains to place a suitable wooden structure in the usual way resting on the two wires, and the bridge is made. Owing to the springiness of the wires, a hand rail is essential. As the breaking strain of the wires is, we believe, more than two tons, it will be seen that these bridges being meant for passenger traffic only are equal to any strain which may be put upon them. As these may be erected as high above the flood mark as the nature of the banks and the timber used will permit, there is no fear of their being swept away. Even should the water rise to the level of the bridge, there being no pillars or anything to offer a large resisting surface to the water, it would merely flow over it. While one of the Mlanje bridges was being erected, and before the posts had been firmly fixed in the ground, a heavy flood came down and the water rose to the level of the bridge."

PLANTING BOOKS.

Map of Ceylon Tea Estates Rs.9; colored Rs.10; Mounted in case Rs. 14. Map of Ceylon Plantations, Plain Rs.8. Inga Va, Rs.2-8. Areca Palm, As.12. Cocoanut Planter's Manual, Rs.4-10. Apply "Observer Office,"
Colombo.

A new Company: Messrs. Davidson and Co., Ltd. We learn from an exchange that Messrs. Davidson and Co., the Sirocco Engineering firm, is being formed into a limited liability Company. We have not heard as yet what the capital is to be, but all the ordinary and preference shares have already been taken up. The latest news from Belfast says that £60,000 worth of debenture shares at £100 each are still being offered to the public, and a telegram recently received by members of the firm's Eastern staff offered to reserve them some of these. To this offer the *employés* are asked to reply by wire, and we understand most of them have taken advantage of it. As far as we know, no shares have been taken up locally. It is estimated by those best able to judge that the capital is somewhere about £200,000. The firm, the head office of which is in Belfast, has branches in Colombo and Calcutta, and agencies in Java, while new ones have recently been started in the treaty ports of China. They are having enquiries for siroccos from all over China, and if the rivers are opened up to free trade, as the result of the present negociations between the Powers, it is probable a big business will be done there. In addition to this a very substantial business is being done in Russia. At the present moment the prospects of the firm are in a better position than they ever were, and we hear that upon the shares being offered by a broker in Belfast they were bought up very quickly without his leaving his office. The firm has hitherto been the sole property of Mr. S. C. Davidson, of Belfast. He was originally a tea planter in Cachar, India, and remained a planter for 14 years. Subsequently he was the proprietor of one large estate and a big shareholder in several tea companies there. The present sirocco business he started about twenty years ago in Belfast. We understand that he has himself taken the larger portion of both the ordinary and the debenture shares. For the debentures, 4½ per cent. is guaranteed, and it is understood that the ordinary shares as well as these are £100. When full particulars arrive in the East, it will be too late, of course, to think of buying shares.

Planting operations in East Africa. In 1891 an Indian planter, Mr. W. W. Fitzgerald, was engaged by the British East Africa Company to establish experimental plantations on the coast lands, and to examine the soil of the great unexplored tract that lies between Lamu and Port Durnford. Mr. Fitzgerald, says the *H. and C. Mail*, has just issued a book entitled "Travels in British East Africa, Zanzibar, and Pemba," in which there is an account of his labours. The Arabs had already established plantations in the neighbourhood of Melindi, but with the abolition of slavery, large tracts of land were falling out of cultivation for want of labour. There were, however, settlements of runaway slaves who were induced to engage as plantation hands by the novelty of a promise of wages, and Mr. Fitzgerald, with that rare combination of tact and kindliness which was conspicuous throughout his dealings with the natives, had a strong and loyal body of labourers at work upon the land within a few months of his arrival. While his crops were ripening, he scoured the country in search of other promising fields, with his eyes always fixed upon the main object of his expeditions. Mr. Fitzgerald takes a cheerful view of agricultural prospects. In the Sabaki valley he found a soil in which cotton, tobacco, sugar, fibre plants, and cocoanuts flourish with

equal luxuriance, which can be tilled with a light bullock-plough, and is never subject to the long droughts of the Indian plains. But the planter has to contend with his old enemy—the dearth of labour. Mr. Fitzgerald would apply the old panacea—the importation of Indian coolies, but he does not say how the Indian Government is to be induced to waive restrictions and safeguards that are greater than any Protectorate is in a position to give, or how, with a minimum wage of a shilling a day added to the cost of introduction, housing, and hospital, the East African planter is to compete with the Indian. With the exception of rubber, British East Africa does not produce anything that cannot be grown in tropical countries where the labour difficulties are less acute, and what has failed to pay in them is scarcely likely to prosper in a colony where the conditions are less favourable.

"Thrips" on coffee.

Some half dozen African exchanges having turned up last week. our notes are somewhat African-tinged in consequence, Has the "Thrips" pest ever been met with in India on coffee? The *Central African Times* has the following remarks on it. Shade, it will be observed, is recognised as a preventative of this as so many other diseases or pests :—

"We are indebted to Mr. Moir for his paper on this coffee pest which has done a great deal of harm this last season. It is not, however, a new coffee pest in the sense that this is the first year in which it has made its appearance here, as it has been noted for some years now, although probably only identified by those familiar with thrips at home. Thrips, we understand, are well-known to British gardeners and farmers, and there is one kind called *Thrips ceralium*, or corn thrips, which does a good deal of damage to wheat. It is described as a very minute, hardly distinguishable insect, which sucks the sap from wheat ears and causes the seed to shrivel. Gardeners are also familiar with it in greenhouses, and they find it is usually worst in dry weather. Mr. Mahon noted the thrips on the coffee estates he visited and, if we are not mistaken, was of opinion that they were due to the drought and would disappear with the rains. We ourselves noticed them about two and-a-half years ago (1895), when the rains at Zomba were somewhat late of coming, and one or two of the fields suffered badly. The puzzle then was to decide whether the damage was caused by the drought alone, or whether there was some pest. After carefully examining the plants, the opinion was formed that the little, almost indistinguishable insects were the cause, but the then head of the Scientific Department could not give any definite information on the matter, although specimens were submitted to him, and he was of opinion that the damage was caused entirely by drought. So far as we can gather, the thrips will not cause very much damage unless the rains are late, but if there is the least drought they multiply exceedingly, and then must do considerable harm. The question therefore is, would the drought without the thrips not do practically as much harm, and if it is granted that the thrips only do damage in times of drought, the remedy would appear to lie in combating the drought and not in trying to exterminate the thrips. It is possible that shade would be a remedy, and so far as our observations go they confirm the possibility, because in all cases in which we have seen fields attacked by thrips, plants in the shade have escaped with little or no damage. This pest also appears to be worst on low, hot elevations and, so far as we know, has not been troublesome on the high-lying plantations about Blantyre. We would, however, be glad to hear what our readers who have knowledge of this pest have to say about it, and Mr. Mahon will no doubt give us the benefit of his observations, especially as to the best means to combat it. Mr. Moir recommends spraying with a sprayer, and if that is to be done, then one of the knapsack sprayers would be the best. They can be got for about £2 each, and are very useful things to have on a plantation for all sorts of plant pests, and would even be of use, Mr. Moir thinks, in the case of *Hemeleia Vastatrix*."

The London Market.

Coffee.—Larger supplies have been brought forward than previously this season, says the *Produce Markets Review* of 26th ultimo and have contained a better assortment of home trade descriptions. In the early part of the week the demand was slow, but towards the end there has been an improvement and it looks as if the lower range of prices was at last attracting more attention, and leading to a better trade. One reason of the poorness of the demand thus far, from the home trade, is the lateness of the arrival of most of the best marks of both Costa Rica and East India. Generally these come amongst the first shipments, but this year the commoner ones have arrived first, and buyers, in consequence, are waiting to see how the better ones will turn out. Prices have been very irregular, but medium sorts are about 2*s.* cheaper, and really fine liquoring Costa Rica can now be bought between 70*s.* to 80*s.* per cwt. In the terminal market continued heavy receipts have led to a further fall, which has been partially checked towards the close, but quotations are mostly from 9*d.* to 1*s.* below last week.

Indian Teas.—There has been a better demand, but as the supplies have been ample, values show very little change. The higher grades attract most attention, and for the rather small selection offered competition was brisk and prices quite equal to, and in some cases higher than those realised in the preceding sales. Many of these teas are of autumnal flavour, not too pronounced, and as it is now evident, from recent reports, that such tea will be in very poor supply later on, buyers are securing these grades in excess of their immediate requirements. Good liquoring medium descriptions have also been readily taken at quite former rates, while some of the better parcels fetched

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

vanced prices. Those who do not hold a good working ock of these grades would do well to take advantage of e gradually decreasing quantity now coming forward, d although they cannot be bought on such favourable rms as a month or so ago, they are still of comparatively ood value. For the common sorts prices are still irregu-r, and a fairly large quantity has been withdrawn from ublic sale, owing, it is reported, to the bids made having een much below the Calcutta cost, although representing e value prevailing in this market. So long as this is the se, holders, by withdrawing their teas, will only inten-fy the difficulty in selling later on, as the stock of this ass is gradually increasing, owing to the large proportion rought by the later shipments. At the public sales 34,855 ackages were offered, and the large quantity of 6,272 ithdrawn.

---

oofs. Which is the best kind of roof for the tropics is a question which one iten hears discussed, and which a writer to the *Central frican Times* answers as follows :—

"Generally the discussion falls into which is the best nd most practical, for one usually finds unanimity on the oint that a tile roof is the coolest, French tiles, for example uch as are found in Quilimane and one or two samples of hich are to be met with in Chiromo. Owing to heavy eight charges, imported tiles have never been practical p-country, so they have usually to be left out of the count. he decision lies between iron and grass, and possibly ocally made tiles may compete for a place. For coolness othing beats a grass roof, but it is supposed not to be so ealthy as a tile or iron roof, and its danger in the case of re is obvious. Further, it requires renewal every three ears at least, as the grass gets rotten and the roof leaks. s advantages are its coolness and the cheapness of the rst cost. Iron, on the other hand, is easily put up, lasts long time, and if well put on is absolutely rain-tight. It so requires less pitch on the roof, and consequently there less surface to construct, and the smaller pitch allows of higher verandah. Against these advantages we have to et the fact that houses with iron roofs are usually much otter in hot weather and much colder in cold weather (and is in spite of good ventilation) and the proportionally igher first cost.

"Tiled roofs are not common in B. C. A., and the reason ssigned is the difficulty of making good tiles. This is a ifficulty which could be got over by introducing a tile-mak-ng machine. With the excellent clay which is everywhere bundant in the plateau lands there seems to be every pros-ect of such a machine turning out excellent tiles, and if the ost was such as to admit of them being sold much cheaper an iron, I believe they would replace most of the grass oofs at present in existence and would be generally adopted n all new buildings, for the advantages of tiles are many. Hitherto the attempts to make them have not, so far as I m aware, been conspicuous successes, unless those made by Mr. Brown at Cholo may be pronounced such. The tiles ade at the Blantyre Mission many years ago and used for oofing part of the school, I am told, were not a great success, nd the experiment was not continued. Given good tiles, omewhat after the style of the French tiles, their advan-ages would be coolness, rain-proof and, we will assume, cheapness. They also make a prettier roof than iron and would last fully as long. Their chief disadvantage is that they require a strong roof to support them, but it may be kept in mind that machine-made tiles are thinner and consequently lighter than hand-made ones.

"I have often thought that the flat roof, which is so distinctive of Eastern countries, would be very suitable for B. C. A., but the difficulties in the way appear to be almost insurmountable. Those who have been in the East, or who have travelled by the north route, must have noticed them frequently. At Zanzibar they are very common, and the delightful coolness of the houses there strikes the observer at once. In Zanzibar they are constructed of a sort of cement made from the coral which is so abundant there, and unless it were possible to make a cheap cement from the lime to be found in the country, I am afraid flat roofs will not become common in B. C. A."

In connection with iron roofs, a Glasgow firm has brought out a cement called "Tilestonite," which it states is suitable for roofs and outside walls of iron and wooden buildings in tropical climates. It is said to be heat-resisting, waterproof and fireproof. The mode of application seems to be to place it on the surface of the iron which it protects from corroding agencies. An iron roof covered with it appears quite flat like a slab of cement. It is said to have been adopted by the Indian Government, De Beers, &c., and the cost, including freight (ocean freight, we suppose, is meant), is put down at $3\frac{1}{2}d.$ per square foot, a ton being sufficient for 500 square feet. It is obvious, however, that to cover iron roofs here with it would make the cost of roofing almost prohibitive. So far as my observations go, I am inclined to think that the tile would be the best for this country.

Camphor distillation. The following letters regarding the product of the camphor tree in Ceylon will be read with interest. The letters appeared in the *Ceylon Observer* :—

GOVT. BOTANIC GARDENS,
HAKGALA, NUWARA ELIYA,
6th April, 1898.

DEAR SIR,—Referring to your question as to what is being done with camphor cultivation in Ceylon, I may add the following to what I wrote you on the 11th of February last. Wishing to satisfy myself that solid camphor existed in the leaves and twigs of even very young plants, I sent a small bundle of prunings, from plants planted out at the end of 1895, to Mr. S. A. Owen, of Messrs. W. Jordan & Co., of Lindula, who had very kindly undertaken to make the experiment for me. I am pleased to state that he has been very successful in extracting solid camphor from them; and as this is of general interest to planters, I shall be much obliged if you will be good enough to publish Mr. Owen's letter in an early issue of your paper.

The prunings from an average plant 28 months' old, as grown here, weigh from 10 to 12 lb.

I have a good many plants that want pruning, and if applied to before the end of this month, April, I shall be very glad to supply 10 or 20, or 35 lb. prunings to any person wishing to make the experiment for himself.—I am, dear Sir, yours faithfully,

W. NOCK,
Supt., G. B. Gardens, Hakgala.

The following is Mr. Owen's letter, Talawakele, March 30th, 1898.

DEAR MR. NOCK,—Thanks for the parcel of camphor prunings duly received. I have made several experiments. The following is the account of methods employed and results :—

(1) Took about 7 lb. of mixture of leaves, twigs and small branches, and gently simmered with about 2 gallons of water for three hours.

Result: a strong smell of camphor pervaded the bungalow, and a small quantity of camphor *oil* collected on the surface of the water, but no solid camphor appeared.

(2) Selected the thickest of the branches (averaging about an inch in diameter) and cut these into small pieces about 4 lb. in all. These chips were put into an empty kerosine tin, and this tin was placed inverted over another kerosine tin partly filled with water, and the joints between the two were luted around to make it steam-proof. The upper tin had a circular hole cut into the top part, and this hole was fitted with a cork and the cork was provided with a glass tube about 2 feet long communicating with a condenser. Heat was applied to the lower tin and soon after water began to boil, solid camphor commenced to form in the tube, and a little while after the latter became blocked. The steam now forced a passage through the various joints, and so the remaining camphor was carried into the air, thus spoiling this trial.

(3) A gallon iron kettle was packed with leaves and small twigs together with about two pints of water. The cover of the kett le was luted on and the spout fitted with a cork, while a long glass tube proceeded from the cork to a condenser. A short time after the steam commenced to flow, solid camphor began to form in the tube until the latter was at length blocked to a considerable distance; there was in consequence a loss of camphor as in previous experiments, but not so much, as the tube was cleared by the application of a spirit flame which caused the camphor to melt and run down. As the result was so promising, I determined to carry out the same experiment, with a definite quantity of material, as below.

(4) Packed the kettle with 1½ lb. of leaves and twigs as before with same amount of water and modified the arrangement, so that no blocking could occur. Applied heat gradually and kept it up for five hours. At the end of this time the sides of the condenser were coated with camphor, and small lumps were floating in the water which distilled over. All the camphor was collected carefully and dried between bibulous paper (to absorb most of the adhering oil). It then weighed 55 grains, which is equivalent to 12 ounces to the cwt. or 15 lb. to the ton.

I think the results very encouraging, as the leaves and young parts of the camphor tree contain but a very small proportion of camphor compared with the trunk-wood. Indeed, I believe that in Formosa and other camphor-producing countries, it is customary to altogether discard the branches and leaves and use the main wood only.

I should think that planters who have young camphor trees coming on here in Ceylon would find it well worth their while to utilise their prunings—especially if firewood is available and cheap, as this latter item would be practically the only expense, beyond the small amount of labour required and the initial expense of a still, which latter could be easily extemporised out of almost any kind of large iron vessel to which heat could be applied. As the camphor tree is a long while coming to maturity, considerations of this kind ought to be borne in mind.

I have pleasure in enclosing a small sample of the camphor obtained. As you will see, it has a rather dirty appearance due to unavoidable impurity and the sample smells of camphor oil, but these are easily got rid of in the process of refinement. I also enclose a small sample of the same camphor partly purified by sublimation.

You are, of course, very welcome to make what use you like of this account of these small experiments, whether by publication or otherwise. No doubt it would be encouraging to those who have gone to the expense of planting up camphor trees to know that there is camphor in our locally-grown trees. I have heard of one or two misgivings as to whether the soil and climate here would favour the information of camphor in the tree.

Yours faithfully,

(Signed) S. A. OWEN.

LETTERS TO THE EDITOR.

TO CORRESPONDENTS.

["A CEYLON WORM WHO'S TURNED."—Very good, but unauthenticated. "BUTTER."—Your letter forwarded to the gentleman concerned.—ED.]

HOW YOUNG PLANTS DIE.

SIR,—Thanks to "D" for kindly supplying his theory tow the solution of the mysterious death of young plants when early rains occur and after drought. I am afraid, however, "D" must be troubled to supply a more tenable theory. plants took up water as mechanically as a dry sponge abs water, then would "D's" theory be a good one to work on. "I theory is altogether too mechanical and contrary to the real cesses of life in plants that even strictly control the amoun moisture taken up by the roots at any time, however much amount may vary in different kinds of weather, at diffe periods of the year, and during different periods of developm and growth in the plants. Under no circumstances do the r of a plant take up more moisture than can be disposed of in s way or other without the enforcement of the cells.

Evaporation from the leaf-surface disposes of all sur moisture even in damp weather.

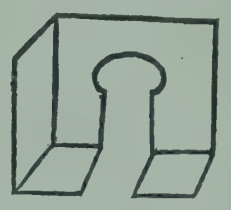
PLANTE

[Only half-authenticated.—ED.]

MR. CLARIDGE'S TRANSPLANTER.

SIR,—Thank you for your criticism on my patent transplan I said the same myself once, but found in actual use—

1*stly*,—That making the transplanters of shorter grade made no difference with the coolie, but it made a difficulty repair, besides being more expensive. In ordinary good nurse they lasted a long time without being damaged, and wit hammer and a bit of round wood were easily kept in or 2*ndly*,—I made a handle somewhat similar to the one suggest—coolies' hands are harder than ours, and they prefer using them without, only with the exception that with 18-i transplanters they were necessary. I annex a drawing of bl I use with and without groove, as suggested by you, 3½ inc



square by 1½ inches deep. But for Europe to avoid stooping, yours would be an advanta You will note it passes round stem of pl over transplanter without having to p it over the whole plant. 3*rdly*.—In weather the plant does not jam or *require* rammer, which I have tried without advantage. If there is a difficulty, it is best to take the ring right off; but it is better to take it off unless necessary, as it lessens the chance of losi them.

To avoid jamming.—This is the object of having the r ⅛ inch less in circumference than the transplanter. The ea that enters is slightly less than its circumference. The split-ri which acts as a spring, helps this and consolidates the ea round the plant with an even pressure similar and better th could be done with the hand.

My object has been simplicity, and to meet as much as possi the coolie intellect.

The Mercantile Mission Branch, Calicut, will quote prices 100 and 1,000, and blocks can also be had for them, but I wo suggest them being made on the estates, as it adds a great d to the expense.

Again thanking you,

GEO. W. CLARIDGE

HAREHATCH ESTATE, *viâ* BODINAIKANUR,
MADURA DISTRICT,
10*th April*, 1898.

I hope to lessen the price very much as soon as I can arra for large quantities to be manufactured at a time.

GENERAL ARTICLES.

THE U. P. A. S. I. SECTION.

[*Under the control of the Secretary, U. P. A. S. I.*]

The currency question is well to the front, and corre-ondence regarding "Planters and Exchange" pours into e columns of the daily press. Meanwhile, be it noted at the Planters' Association of Ceylon and the U. P. A. S. I. e by no means idle with respect to this subject. The eylon Association made certain representations to the cal Government lately, and, as a consequence, the Governor s despatched a telegram to the Secretary of State for the olonies, urging the representation before the Currency ommittee of the producing interests, Native as well as uropean. In a letter from the Colonial Secretary, Ceylon, the Planters' Association, it is remarked that these terests "are unfortunately in apparent conflict with those the Indian Government." For the right protection or presentation of Ceylon interests, it has been suggested by e Governor, in the telegram referred to, that they should ave a voice in the enquiry through Mr. T. N. Christie, ther as a member or as a witness.

The interests of Ceylon must, as its Government observes, be the same as those of a large part of India," so it is well at the Planters' Association of Ceylon should have emorialized the Secretary of State for the Colonies, as it d a fortnight ago, regarding "the extreme gravity of the xisting conditions of exchange and currency, and the sastrous results of the artificial high rate." The memorial ludes to the present position as intolerable, and urges at Government should take such steps as shall be final, fter instituting a "fresh, impartial and exhaustive enquiry which the producers will not be sacrificed, but will be lly represented."

In like manner, the U. P. A. S. I. has expressed to the overnment of India a desire for a fair hearing, and it is oped that arrangements will be made whereby one witness more will be allowed to give evidence before the Com-ittee as to the position and needs of the planting com-unity in Southern India. If the Secretary of State for ndia permits this course to be taken, a selection will be ade from among the most influential planters who may appen to be in Europe at the time. The Secretary of the . P. A. S. I. would be glad to receive information as to e names and addresses of such gentlemen, so that as omplete a list as possible may be laid before the Chairman.

It is of the utmost importance that whatever is done ould be done promptly.

6. *Read* and *Recorded* letter No. $\frac{458}{L.\ F.}$, dated 23rd March, from the Collector, saying that he sees no necessity to reconsider his decision that a Planting Member of the Taluq Board was not required, as Yercaud was not now under the Taluq but the District Board.

7. *Read* copy of a letter from Mr. H. O. Newport, dated Brisbane, 6th March, 1898, circulated by the Secretary, U. P. A. S. I., reporting his movements in quest of Lady-birds.

8. *Read* letter No. $\frac{R.\ W.\ 7,\ No.\ 6}{37611}$, dated 26th March, 1898, from the Postmaster-General, saying that he considered it impracticable, under the circumstances, to throw the Mail bags out of the train at Kadiampatti, but that if the planters were willing to make up the difference in cost, paying for six months in advance, he would be prepared to have the Mails conveyed by runners from Mallapuram instead of from Kadiampatti.

Resolved that the Honorary Secretary be requested to address the Agent and Manager of the Madras Railway, and to ask him to arrange either to stop the Mail train at Kadiampatti, which would be a great boon to the planters and others, or if that be not possible, to inquire whether he could not put up an apparatus similar to that used in England and other countries whereby the trains would automatically receive and discharge the Mail bags; as if he could do that, it would probably satisfy the Postmaster-General.

The following papers were laid on the table:—

Proceedings of a General Meeting of the Lower Pulneys' Association, dated 12th February, 1898.

Proceedings of a General Meeting of the Wynaad Planters' Association, dated 2nd March, 1898.

Copies of *Planting Opinion*, dated 19th and 26th March, 1898.

Robert Gompertz,
Hony. Secretary.

C. G. Lechler,
Chairman.

CENTRAL TRAVANCORE.

A General Meeting of this Association was held at the Penshurst Bungalow, at 10 A.M., on Saturday, the 9th April.

Present:—Messrs. H. Arnold, F. Bissett, H. J. Blandford, K. A. Burne, R. W. Cole, R. W. Courtenay, L. W. Crawhall, R. H. Goldie, C. N. Grimshaw, R. S. Imray (by proxy), H. S. Holder, L. G. Knight, W. H. Leaky, B. Laurie, P. Montgomery, D. MacArth N. Macgowan, W. H. M. Macgrath, H. S. Place, W. W. Sloco A. E. Veale, Hon. V. B. Wilbraham, F. M. Parker (*Chairman*), a H. W. Baker (*Honorary Secretary*).

Honorary Members:—Messrs. J. S. Sealy and A. W. L. Verned

Visitors:—Messrs. H. D. Deane and C. H. Ewart.

Read notice calling meeting.

The Chairman, in opening the meeting, expressed his pleasu at presiding over such a large attendance and his gratification the interest shown by members in the affairs of the Association.

Minutes of last meeting were taken as read.

Read Madras Government Proceedings, in reply to the late Hon rary Secretary's letter forwarded by the President, Madura Lo Fund Board, regarding alternative schemes for repair of, or re-alig ment of, *Kumili-Peermaad ghât road* and the Pulliar-Suttu brid Resolved that the Secretary write to the President, Local Fu Board, requesting information as to when the repairs would probab be completed, as this Association understands that the flow of wa through the Pulliar-Suttu bridge has now ceased owing to t closing of the supply sluices on the Periar Irrigation Works.

Coast Shipments.—Read letter from Messrs. Aspinwall & Co. Chairman, dated February 26th, 1898, and Chairman's reply to sa with reference to the shipment of produce on the coast. After discussion in Committee, it was finally resolved that the Chairman requested to communicate with Messrs. Aspinwall & Co., stati that the Association, as a body, is not unanimous in the matter, a that consequently shippers would make their own arrangements the present.

Extension of Telegraph Wire.—*Proposed* by Mr. Holder, a *seconded* by Mr. Laurie, that the Honorary Secretary communica with the Director-General of Telegraphs, Calcutta, requesting that t telegraph wires be connected between the Peermaad and Kum stations, a distance of 22 miles by road, and probably 15 or so acr country. This line would not only be a very economical one construct (as no stations would be required), but it would affor direct through line from the West Coast to Madras and the East divisions of the Presidency.—*Carried.*

Stamps on Telegraph Receipts.—*Proposed* by Mr. Holder, a *seconded* by Mr. Laurie, that an enquiry be addressed to t Director-General of Telegraphs as to whether telegraphic stam could not be attached to *all* telegraph receipts (both inland a foreign) at *all* "combined" Postal and Telegraph stations (inste

With a vote of thanks to the Chairman, the meeting then closed.

H. W. Baker,
Hony. Secy., C. T. P. A.

A Committee Meeting of this Association was held at the Penshurst Bungalow, at 9 A.M., on Saturday, April 9th, 1898.

Present :—Messrs. F. M. Parker (*Chairman*), R. H. Goldie, B. Laurie, A. E. Veale (*Honorary Secretary, Medical Fund*), H. W. Baker (*Honorary Secretary, C. T. P. A.*)

Read correspondence regarding Glenmary Apothecary and letter from him explaining the delay. Letter recorded. Resolved that a Committee, composed of the Chairman and Secretary, interview the chief medical officer with respect to complaints, and to decide on the necessary steps for the more punctual despatch of work. *Proposed* by Mr. Baker, and *seconded* by Mr. Parker, that with the intention of bringing the Medical Fund Leave rules into accord with the Government Medical Grant-in-aid rules, that the former be altered in so far that the one month's annual leave, sanctioned to the Medical Fund officers, can only be availed of by them in periods of 14 days at a time, or less, for each absence from their stations.—*Carried.*

Read letter from Mr. R. W. Cole *in re* proposed additional accommodation in Doctor's house for medical stores. Resolved that medical stores be kept under lock and key at local dispensaries.

Grant-in-Aid.—Proposed that the Honorary Secretary, Medical Fund, be requested to communicate with the Dewan with reference to the payments now due.—*Carried.*

With a vote of thanks to the Chairman, the meeting closed.

H. W. Baker,
Hony. Secy., C. T. P. A.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (April 1, 1898) says :—Heavy supplies have again been catalogued and values generally are rather easier; fine qualities, however, were well maintained.

Nearly 2,500 bags East India were offered and mostly sold. Neilgherry met a poor demand and was difficult to dispose of at 2/– to 3/– decline, whilst a fair proportion had to be bought in. Fine Home Trade marks, however, attracted keen competition and realised extreme rates.

The large quantity of Central American brought forward sold slowly at declining prices for all descriptions except the colory grades, which show no change.

Futures have recovered 2/– during the week, chiefly in consequence of dearer cost and freight offers and reduced Brazilian stocks.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending March 30th, 1898, says :—Bank rate 3%. Bombay Exchange closes at 1s $3\frac{2}{32}$d. Brazil Exchange $6\frac{1}{16}$d. Rupee paper $3\frac{1}{2}$% $62\frac{1}{8}$. Silver $25\frac{11}{16}$d per oz.

Further extensive supplies have been brought forward since our last report; these have met with a poor demand for all kinds, except finest, and have only been partly sold at a further reduction of 1s to 2s per cwt. Fine East India continues to sell with competition, but the commoner kinds, such as grayish and foxy Wynaad, are almost unsaleable, and have been mostly withdrawn. The bulk of the Central American supplies has been of poor quality, and to effect sales, considerably lower prices would have to be accepted. At the close the tone is somewhat better, and there seems to be more inclination to do business at the low values now ruling. Brazil markets are steady.

Daily receipts averaged 9,300 bags in Rio and 13,100 bags in Santos.

Futures have been firmer, and close 6d to 9d per cwt. dearer, viz. :—Good average Santos in Havre, May delivery, fcs. 34.75, in Hamburg pf. $28\frac{3}{4}$, and No. 7 low ordinary Rio in New York $5.30.

To-day's London official quotations are :—

	April	May	July	Sept.	Dec., '98.	Mar., '99.

TEA.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, dated April 1st, 1898, says :—

QUANTITY BROUGHT TO AUCTION IN LONDON

From 1st June to Date.

	Indian.	Ceylon.	Java.
1897-1898...	1,429,024 packages.	1,002,220 packages.	37,008 packages.
1896-1897...	1,445,413 ,,	941,594 ,,	37,334 ,,

28,503 *pkgs.* Indian
26,615 ,, Ceylon
1,554 ,, Java

Total 56,672 packages were offered in public auction this week.

The present depressed state of the market is disappointing to all concerned in Tea production. Home Consumption progressed steadily for several years, but duty payments commenced to fall off towards the close of 1897, and since continued almost without interruption, viz. :—

	Oct.	Nov.	Dec.	Jan.	Feb.	Total.
1897-8	...19,572,410	20,423,310	17,881,167	19,421,688	17,771,818	95,070,493
1896-7	...21,456,202	20,672,420	19,151,891	19,343,318	18,087,721	98,711,552
1885-6	...20,785,806	20,470,451	16,974,647	20,505,320	17,454,473	96,190,697

It is difficult to assign a positive cause, but various influences may have contributed towards it. The late Engineers' strike involved the loss of enormous sums of money to the wage-earning classes and curtailed their expenditure, as well as the purchasing power of tradesmen affording them credit. This may be partially answerable for the heavy bonded stocks, held mainly by wholesale firms and importers. There are also indications of increased use of cocoa which may possibly have interfered with Tea consumption.

It is gratifying to note that Tea clearances during the month of March have shown larger duty payments; it seems therefore probable that whatever influences have been at work may prove only of a temporary character and that some improvement in prices may therefore be anticipated.

Indian. There is very little change to record in the market, the bidding showing a somewhat languid tendency. 153 closing invoices have been printed, against 225 last season. The following averages may be mentioned:—"Chardwar T Co. Chardwar," 1/0¼; and E. M. P. T. Co.'s gardens "Borjulie" and "Sonajulie," 11½d.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, ht Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including tage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for advertisements will be: 4 as. per line for the first, 3 as. for the second, 2 as. for the third and succeeding insertions. Five-line advertisements n Subscribers will be inserted for three issues for one rupee; non-Subbers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic urrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," lanade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been moved to Madras, all remittances should be made payle to the Manager of *Planting Opinion*, 11 and 12, cond Line Beach, Madras, who will also attend to all vertisements, &c.

Letters to the Editor should be addressed to Coonoor, usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 6th May, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

SEASON REPORTS.

Lower Pulneys.

DINDIGUL, 26*th April.—Weather.*—Good rains all over the district since 17th April, average about 5 inches. *Crops.*—Magnificent blossoms out everywhere. Crop promises to be large for 1898-99. *General Health.*—Fairly good. *Labour.*—Plentiful.

S. E. Wynaad.

27*th April.—Weather.*—The cry of the spikes made the skies to pour down the rains. We have had a few showers on the 23rd, 24th and 25th, but did very little good. Since yesterday the clouds bank up in the evening, but the rain does not fall. During the day it is very hot. The spikes on some places all burnt and gone and in some places reviving. *Health.*—The diseases stated in my last report are still prevalent.

Coorg.

POLLI BETTA, 26*th April.—Weather.*—The rain reported last week was followed by more on 21st and following dates up to Monday, 25th, inclusive. In many cases the requisite quantity was made up by falls of from 10 cents to 40 cents. Out east, however, there was heavy rain on Friday last, the 22nd, amounting from 1 to $2\frac{1}{2}$ inches. All this came down in about two hours' time. *Crops.*—In every case where rain was 15 cents and over on Monday, 17th, the blossom was started, and some of it was open on Sunday and Monday last, but the great bulk will be out on Friday next or so. The rain seems to have been quite seasonable. There is a most magnificent show of blossom on nearly all places, and prospects are extremely good, conditions being favourable for a good set. *Public Health.*—Good.

Nilgiris.

COONOOR, 27*th April.*—Since last Wednesday I have had 1·03 inches of rain

quite enough for the present with what has come before. Coffee blossom in many places is turning out a great success, but how estates have had a certain proportion of young crops burnt off of the previous drought. Generally speaking, everyone seems happy. Tea is already responding to the rain, and may catch up arrears yet. General health better since the rain has fallen. I hope I won't hurt anyone's feelings, but I do wish weather-moonists in your reports would attempt to explain *why* they refer to the moon and its alleged connection with the weather. Because it affects the tides? But the moon affects the tides at certain and very definite periods. Is this the case with the weather? It's the dull season now; no work and lots of time. Suppose one of your weather correspondents starts some interesting subject to discuss, strictly, of course, confined to our select little band. Difficulty, of course, is—subject.

Kullakamby, 27*th April.*—*Weather.*—Good rain has fallen and brought out the spike. A good deal of blossom is already out, and the cloudy weather still continues and more rain may be expected. *General Health.*—Fever prevalent somewhat, but general health good.

VEGETABLE PESTS AND BLIGHTS.

In Dr. George Watt's new work on "The Pests and Blights of the Tea Plant,"* planters—whether of tea, coffee or any other product—will find plenty to interest and instruct. The book is of course primarily devoted to the pests and blights of the tea plant, and, in fact, is a report of a short investigation in the Assam and Kangra tea-districts undertaken for the Indian Government at the instance of the Indian Tea Association. The investigations were cut short, we believe, by Government, as it considered that the Indian Tea Industry could very well afford to pay its own scientific officers. Still, short as was the duration of his field labours, Dr. Watt's book bears ample evidence—467 pages of it—of the great interest he has taken in the work, and lays down clearly enough the lines on which future investigations should take place.

We shall not here touch on the varied forms of blights and other pests that afflict tea, but shall rather consider the broader lines of the treatment of blights applicable to plantations generally, be the staple what it may. It is a point of particular interest to observe that, despite repeated and keen search, Dr. Watt was unable to discover any of the more important blights on any of the wild tea growing in the Naga Hills. This observation, confirming as it does the generally accepted opinion that crop diseases are due very largely to the artificial conditions under which they are grown, strikes the keynote of Dr. Watt's convictions regarding the proper treatment of pests. It is possible, he admits, to cure fungoid or other diseases by fungicides and other poisons, but the aim of the up-to-date planter should be to strike at the rost of the evil, *i.e.*, to remove the cause of the disease itself by improved cultivation, manuring and pruning. We have a certain pleasure in reminding our readers that this standpoint is identically the one which we have always taken, one in fact which we share with many of the most progressive planters of the day.

To arrive, however, at a correct understanding of the precise conditions of environment that favour the development and attacks of plant pests, an intimate knowledge is r quired of the life history of the insects or fungi which a under treatment. The dense ignorance that still preva on this subject of, for instance, the red spider on tea something astonishing. When the immense annual pec niary loss suffered from its ravages is taken into accou it is difficult to believe that no one can yet know whe the insect hibernates. Yet it is likely that if this we known, and a half dozen simple experiments extending ov a few years would solve the point, the effectual treatme of the pest would be quite within the limits of planti operations. It is the same with the mosquito (*Helopelti* No one knows where it goes to, when its work for the ye is over, nor where it comes from to begin its operations the next season.

As stated before, the cultivation of most crops is a companied by a very great difference in the influences which the particular plant is subjected to in its wild sta Nowhere, perhaps, is this more strikingly the case than wi the tea bush. The entire nature of the plant has be changed under cultivation. Fruiting is rigorously su pressed by all known means of treatment, and the two three scanty crops of young leaves borne when wild in t jungles is forced up to thirty or more crops in the year. fact, it is scarcely too much to say that, under the prese system of cultivation, success consists in the production and development of a diseased state. It is no wonder th that old gardens, unless very carefully and regula "supplied," exhibit undoubted signs of serious deterior ion in every way. Coffee exhibits the same results in even more striking way.

To state that, under the present system, success mea exhaustion, does not imply that equally great success, *i.* large and good yields, cannot be obtained by a different a more intelligent treatment without its now inevita consequence of exhaustion. Dr. Watt states that, w exception of one or two of the blights, and more especia in cases where these blights had only recently appeared any serious extent, he did not find a garden in Ass badly blighted in which the bushes did not show that th were in an unhealthy state, altogether apart from peculiar malady with which they were at that particu time beset.

By way of impressing upon tea-planters the great r which they may run in neglecting to extirpate apparen insignificant blights, the well-known ruin of the Cey coffee industry by coffee disease is cited. That this dange by no means imaginary Dr. Watt shows by instancing va ous forms of tea-blight that are spreading almost unnotic in the tea districts, being gradual in their action and significant in their appearance. It is mournfully interesti to notice that a very large percentage of the insect pests the Ceylon coffee plant have been found doing considera damage to tea in India.

Returning to the subject of combating disease by i proved methods of planting, it is urged that far too lit care is observed in obtaining good seed even from the called seed gardens growing in spots remote from danger hybridisation with inferior stock. The cultivation is usua merely nominal, while the treatment of the trees themsel is wanting in several important respects. From this st of things to that advocated by Dr. Watt, *i.e.*, the establi ment of seed gardens to procure disease-proof plants

* "Pests and Blights of the Tea Plants", by George Watt, M.B., C.M., F.L.S., C.I.E., &c. &c. Published at the Office of the Superintendent of Government Printing, India, Calcutta. Price Rs.2-8-0.

perior cropping power, is a very long step indeed. Yet, any one with even a nodding acquaintance with the results modern agricultural research in this direction, it is obvious t such efforts would be almost certainly bound to be wned with success. Entailing, however, as this work does, g and patient investigation by trained men, we think this uld in all fairness be taken up by Government. The ditions of the planting industry are such that it would almost impossible to conduct the needful experiments in uccessful manner by private enterprise. Short of Governnt aid, combined effort in the shape of suitably endowing requisite research stations is the only alternative. This ans money of course. And just now low prices and high change have rendered this commodity fearfully scarce. This alone does not profess to be a complete review on Watt's work, but such as it is, we hope interest will e been aroused in the work which we repeat will be nd valuable by all planters, whether engaged in the tivation of tea or of any other product.

NOTES.

ing freights. This year's big grain crops in India are adding yet another straw, and a y substantial one, to the huge load of the planter. Besides large crops, the coal-strike at home will probably ect competition and cause freights to go higher still. eights are rising steadily. In Calcutta they have advan- to 22*s.* 6*d.* Colombo rates are 25*s.* already. In August 96 they fell to 7*s.* 6*d.*; the mean rate is about 20*s.* A ference of £1 sterling per ton makes as much as a thing per pound difference in the cost of getting tea on London market.

---

erest on advances. Among the signs of the hard times now ruling in the planting rld may be cited the late abortive attempt in Mysore to uce cooly wages, and the present movement in Ceylon to rge interest on all advances made to coolies or maistries er than those advances for recruiting labour. In ylon an evil custom has grown up of issuing advances to ble the maistry or coolies to pay their bazaar debts, en amounting to very large sums. It is on these advan- that interest is to be chargeable. It would seem far er to combine against giving these advances at all. In dia we are luckily free from this sort of extortion.

---

e American Fund. In issuing the now annual call for subscriptions to provide funds the important American market, the Indian Tea Asso- tion draws attention to the great success already achieved America from the working of the campaign. America sorbed over 11¾ million pounds of British-grown tea last ar (India and Ceylon contributing almost equal shares) ainst a little over 3 millions in 1892. Last year the bscriptions amounted to Rs.1,05,000, against Rs.1,03,000 1896. The rate of subscription is the same as before, , 4 annas per acre of tea and half an anna per maund 2 lb.) of manufactured tea.

---

nitrogenous manure eeded? This is the question which Mr. Baur, of the Ceylon Manure Works, is asking the Island planters with ference to the subject dwelt in our issue of last week in the article headed "Nitrefying Earth as a Manure." Mr. Baur holds that in view of what he alleges to be the exceptionally favourable conditions for nitrefaction that rule in Ceylon, planters of that ilk might well neglect the matter of nitrogenous manures. On the other hand, Mr. Baur advises that far greater attention should be paid to supplying local crops with mineral manures in a soluble form. Raw bones are all very well, but not half soluble enough, and interest is lost on the necessary expenditure of capital.

Indian tea exports. In the current monthly tabular statement of tea exports given by the Indian Tea Association, we note that the past season's crop has totalled over 148¼ million pounds against under 147¾ M. for 1896-97—a very slight increase. The shipments to Great Britain were 133¾ M., proportionately the same as the previous season. Australasia shows about ½ M. as increase, while the American shipments show a decline of ⅖ M. These figures of course only represent direct shipments. Ceylon has exported 28 1/10 M. from the beginning of the year to the 5th instant compared with 27 1/10 M. last year. March shipments of Indian tea to America are gratifying, being almost 77,000 lb. against only 9½ thousand lb. last year.

Shade and tea. Tea planters in Ceylon are bothering themselves muchly over the subject of the alleged deterioration of their product. The latest suggestion advanced in explanation thereof is the effect of the shade cast by the numerous trees planted by the sides of roads and, in belts, in the tea itself. The *Times of Ceylon* considers this suggestion very strange, and cannot understand how the quality of the leaf produced from the tea in the vicinity of shade trees could be affected. In India at least there is now held to be no possible doubt on the bad effect of shade *quâ* shade on the quality of the leaf, which when manufactured gives a thin, pale liquor with neither strength nor aroma. Whether the proportion of shaded tea in Ceylon is such as to affect the whole yield is of course a very different matter.

Nyassaland coffee. Mr. Trubridge, a Ceylon planter, has given his impressions on the capabilities of Nyassaland as a coffee district to the local organ, the *Central African Times*. He went out from London specially to inspect the country. The climate he found to be better than its reputation (which from most accounts is very vile). The weediness of the coffee fields attracted his unfavourable attention of course, and in a dry country like Nyassaland, we thoroughly agree with the advisability of the Ceylon clean-weeding system. For leaf disease Mr. Trubridge kept a very sharp look-out, but was unable to detect it anywhere in the country. *The* great and universal mistake was of course pointed out again, *i.e.*, the folly of allowing young trees to overbear. Mr. Trubridge thought that 2 cwt. an acre average crop, with the cheap land and cheap labour, would give a very good profit. Lucky Nyassaland!

The beginnings of plants. In one of his recent lectures, Professor Ray Lankester showed that the primal difference between plants and animals was based upon what each was able to eat. The organisms which can only eat substances of

lower chemical elaborateness than starches, sugars, and albumens are said to be holozoic; and all animals belong to this class. Those who can eat oxygen and carbon and nitrogen, and have the power (with the help of chlorophyll and sunlight) of separating oxygen, are called holophytic. But between these two comes the anomalous class—the organisms which have a mouth and eat animal's food, and yet have chlorophyll corpuscles to enable them to get sustenance as the plants get it. These, we say, are saprophytic, and it is among such organisms that we have to search for the point where the animal world and the vegetable kingdom start. There is a green plant called the Englena which has a mouth, and yet has the chlorophyll corpuscles which would class it as a plant; and there are among the tiny organisms of the "flagellata," or whip swimmers, several we should class as animals, and yet which have the green corpuscles in their minute structures. This is, therefore, one reason for believing that it was among the "flagellata" that the vegetable kingdom first found its origin. Broadly speaking, said the professor, one might say that if in the beginning a group of "flagellata" joined themselves end to end so as to form a thread, they turned into a plant; whereas if they followed more complex courses and joined together in more elaborate structures and households, they became animals.

A tea-broker on tea-making.

Mr. G. Stehn, the Manager of the Tea Department of the great Mincing Lane firm, Messrs. Wilson Smithett & Co., has recently paid a visit to the Ceylon tea estates, and is continuing his tour to visit the South Indian gardens. His impression so far of Ceylon manufacture is that planters are not in proper touch with the London market. For instance, the London demand is a for a strong well (not over) fermented tea, whereas most of the Island teas are made on the lines of a few years ago, *i.e.*, very lightly fermented. This is partly due to the Colombo buyers still preferring that quality, mostly for export to America, Australia or the continent. Such teas, however, will not do for London, but the Assam style should be followed. From this censure Mr. Stehn excepts say the teas made in July and August, as their pungency is acceptable. But underfermented teas made in the droughty months are washy and without special point. In the course of an interview published in the *Times of Ceylon* he said that "another thing that struck him was that tea on the whole was made on rather hard and fast lines without due regard to the exigencies of climate. "I mean to say," he said, "that the different factories should not turn out tea on the same lines, but should treat it differently in consideration of climate, elevation, temperature, and other things. Then again, I think sorting in grades requires more attention. There is too much similarity amongst the grades as a rule. Take broken pekoes, for instance. They are not, as a rule, a distinct enough grade. We want a greater proportion of it, true broken pekoe. What do I call true broken pekoe? It is really the fine part of the bulk sorted out, and it must be a comparatively small proportion of it. In several places I noticed they fired the teas too briskly. Brisk firing is all very well for strong low-grown teas, but with these light, delicate, up-country teas it will not do. Quick firing seems to destroy the flavour and all point of the tea. If teas grown at a high elevation were fired slower, I think th flavour would be more prominent."

London Market.

Coffee.—Although the Brazilia exchange has further fallen to 6 (*P. M. Review*, 2nd April), the value of good average Santo offered on cost and freight terms, has advanced about 1*s.* 6 per cwt. This has led to a larger business in the termin market, where values have steadily risen, closing about 1*s.* 6 to 1*s.* 9*d.* above the recent lowest prices. At the auctio there has been a much better demand, and the depressi which characterised the market for the last fortnight more has entirely gone, and, with keener competition, pric are generally dearer. The sales have consisted principal of Costa Rica and other Central American sorts, and, importers are still for the most part anxious to sell, near the whole were easily disposed of at rather irregular rate but in many cases from 1*s.* to 2*s.* above the low quotations last week. Only a small quantity of East India has be offered and sold at about previous rates. The Dutch Tradi Company have advertised their next sale for Tuesday, wh 20,950 bags and 60 cases will be offered, against 19,059 ba and 40 cases at the corresponding sale last year.

Indian Teas.—The bulk of the tea brought forward h been of inferior quality, and owners have found it diffic to dispose of their supplies, even at the present low quotatio The market is, no doubt, overburdened with common d scriptions, and the lower prices current during the past fe weeks have failed to stimulate the demand to any mater extent, from which it may be inferred that the public a prepared to pay a reasonable price for good tea. This is matter that should not be overlooked by those interested the next season's production, as by avoiding, as far practicable, the excessive supplies of the common sor both producer and the trade would benefit. Anoth important point is the quality of the material in which t

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain p ton:—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed fr the parent trees of above analysis at Rs.6 per pound containi about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere s from the

MANAGER, ARIENKOW ESTATE,
Shencottah

tea is packed. Many parcels during the past season have been packed in unsuitable wood, which when it comes into contact with the tea imparts to it, what is termed by the trade, a "cheesy flavour." This should not be difficult to overcome, as the wood giving the contents of the package this peculiar smell is easily detected, and should under all circumstances be strictly avoided. In each case when the tea is in the condition described, it should be printed with all faults, which would not only save time, but would prevent a good deal of friction between buyer and seller. At the public sales 26,892 packages were brought forward and 3,090 withdrawn. For all desirable grades prices were steady with an upward tendency for the finer tea, while the common kinds sold irregularly and occasionally easier.

GENERAL ARTICLES.

THE U.P.A.S.I. SECTION.

(Under the Control of the Secretary, U.P.A.S.I.)

The following is Mr. H. O. Newport's second narrative report, dated Brisbane, 2nd April, 1898, in respect to the Lady-bird scheme :—

Dear Sir,

I have received no letter from you, as I expected to do, by either of the last two mails.

I received a letter from the Hon. Sec., L.P.P.A., however, with several enclosures, and replied to it on the 20th ultimo.

I regret that I was not able to write to you by the same mail, but in writing now, at the end of the month, I can send you, at the same time, accounts of money expended as requested by you.

On the 20th ultimo I was very much out of sorts, and found myself unable to write more than the one letter to the Hon. Sec., L.P.P.A., copy of which, I presume, will have been sent to you. During the subsequent week I had to call in a doctor, who told me that I had the dengue fever, which is very prevalent about here just now, and which appears to be a form of influenza. Hence my silence last mail.

The Hon. Sec., L.P.P.A., in his letter to me, dated 20th February, 1898, informed me that (1) no consignments of Lady-birds need be despatched before my departure from here. (2) That future consignments will be decided upon after my report on those I bring, and (3) that my head-quarters on return are to be the Lower Pulneys.

He also added that the amount to the credit of the fund was on no account to be exceeded, which I think was unnecessary, as you had already impressed this point upon me before my departure.

Mr. Fred. Gerrard enclosed a copy of your letter to him of the 5th February, 1898. This was in reply to a letter you had received from him, dated 1st February, 1898, but copy of which Mr. F. Gerrard does not enclose.

I note that you say I must have misunderstood instruction with regard to the Chairman's suggestion of correspondence with the Hon. Sec., N.P.A. and L.P.P.A. I very much regret that I should have done so and not have *waited for replies* before starting. I do not still see that any benefit would have accrued to the scheme by any further delay however; everything else being settled, these were comparatively minor points, and I can act on the replies, having received them out here, just as satisfactorily as if I had waited to receive them before starting. Moreover, any further delay would have, as it happens, and as I suspected, endangered the success of the scheme.

I admit the instructions, but submit that I fully carried out the spirit of the Chairman's instructions, though I may have not kept strictly to the letter. I trust Mr. Fred. Gerrard will see it in this light.

I note what you say *re* making arrangements for subsequent despatches (should they be needed) through the Department of Agriculture, and I will, I think, be able to do this.

Mr. F. Gerrard also enclosed a copy of a letter from the Hon. Sec., N.P.A., also in reply to one of his, copy of which he does not enclose. I am, therefore, left to conjecture what Mr. Gerrard said.

Mr. Windle's remarks with regard to subsequent work in connection with the experiment seem very just.

I personally understood that I was to go back to the estate I have been in charge of, and was certainly prepared to continue experiments in this line while there. I did not understand that the Nilgiris Plantations Company had ever raised any objections to this. I left them on *leave* (without pay) for as long as may be necessary, up to six months, and understood that they only objected (and very naturally) to my drawing salary from them while I was *out of India* or away from the estate where I could continue my ordinary work, and a substitute had to be provided.

The Hon. Sec., L.P.P.A., seems to have taken things into his own hands, and obtained permission from the Managing Director of the N. P. Coy., Coonoor, for me to use the Pillavaly Estate bungalow. Unless some correspondence has taken place between the Managing Director, N.P. Coy., and the Hon. Sec., L.P.P.A., that I know nothing of, I fail to see why this was necessary. Still less so since it has been decided that the Pillavaly Estate is to be my head-quarters on return, what I am to understand from this I cannot tell.

With regard to the work, I beg to report that everything is going on satisfactorily. I have made several excursions to outlying districts, Government giving me free passes over the Railways, and have identified and named several varieties that I propose to bring over to India, besides the *Cryptolæmus Montrougerii*. The variety *Rhigolius Ventralis* I have found, but it is somewhat rare, and although I will bring all I can get, I do not expect to find many. There are several varieties of *Orcus*, particularly *Orcus Australia*, that Mr. Tryon advises my bringing over, and judging by the good work they are doing here on various scale pests, notably *Ceroplaste rubra*, I am of opinion that they would be of great use to us in India both for the soft shelled Green Scale *Licanium Viride* and the black bug *Lecanium coffee*.

I have all the apparatus necessary except the ice chest, which I am making arrangements for now. This will cost some £5 or so I expect, but it is necessary, as I have to keep the insects some time while I bring in the consignments from different parts and collect them. Moreover, it will be necessary on the voyage, as I hear it is somewhat risky using the ship's refrigerators.

To ensure as far as possible every success, constant attention will be necessary on the voyage back and a uniform temperature of 40° F. or so.

I cannot yet tell when I shall be able to leave. My departure depends upon the collections I shall be able to make this month as well as upon the state of the weather here. I hope, however, to have finished by the end of this month.

Finance.—I beg to report that up to the end of March I have only had to draw £25 from the Circular Note for £160 that you gave me. I have paid all expenses out here, and ended March with some £4 in hand.

Unless I have unexpected and heavy expenditure, I hope to bring back in cash at least half of the sum to my credit here in the Circular Note I carry.

The expenditure, roughly, has been as follows :—

Receipts.	Rs.	A.	P.
From Mr. Ronaldson	1,500	0	0
Total ...	1,500	0	0

Expenditure.	Rs.	A.	P.

I have the honor to be,
Sir,
Your most obedient Servant,
(Signed) Howard Newport.

GREEN MANURING.

A paper on the subject of Green Manuring, devoted mainly to an account of the 40 years' experimental work carried on by Dr. Schultz on his estate at Lupitz Altmark, Saxony, appears in the recently published seventh volume of Mons. Grandeau's "Etudes Agronomiques." The investigations of Dr. Schultz are particularly worthy of attention at the present time, when so much interest is being concentrated on the work of Hallriegel, Wilfarth, Nobbe and others, on the *assimilation of free nitrogen* by leguminous plants,—a subject already well discussed in this journal. The work of Dr. Schultz established facts, the explanation of which was reserved for the recent study of the investigators already referred to. The Lupitz estate with its development, described by Mons. Grandeau, offers an instructive example of the economic transformation of a *poor* into a *fertile* soil. When inherited by Dr. Schultz in 1855, it was for the greater part mere moor and heath land. The soil is a light alluvial one, consisting chiefly of fine quartz or sand, interspersed with grains of felspar and mica, containing but little clay, and naturally very poor in the elements of plant food. It contained only 0·18 to 0·26 per cent. of lime, the subsoil being as sandy as the surface soil. The district has an average rainfall of about 27 inches per annum, and but for this fairly abundant rainfall its cultivation would present still greater natural difficulties since the soil is but little retentive of moisture.

In 1855 the soil could scarcely be said to be "cultivated." It was only by the aid of extraneously produced dung that it was possible to obtain any crop at all, and such produce as the land yielded scarcely paid its expenses. The proprietor, however, happened to notice that while other crops were grown with such difficulty, yet yellow, white and blue *lupines* were an exception to the rule and yielded a moderately good crop as long as they got a fair quantity of rain. Why this difference between lupines and other farm crops? And could it be turned to account to produce other crops fitted for the nourishment of man, and how?

These questions presented themselves to the mind of Dr. Schultz, who, for 40 years, has given himself up to striving to answer them. By long and patient trials he has worked out what throughout Germany has become famous as the "Lupitz System" of cultivation and manuring, which has resulted in transforming the nearly *sterile* sand of 1855 into a fertile estate yielding profitable crops.

The basis of this transformation has been the culture of leguminous green crops, notably lupines, with the aid of mineral manures—lime, potash and phosphates *without the use of nitrogen;* the mineral manures being usually applied not to the leguminous crops themselves, but to the non-leguminous with which they were alternated. To decide what are the best catch crops or green crops to be used for this purpose of green manuring and to trace out the causes of their good effects has been the life work of this celebrated agriculturist.

In 1865 Dr. Schultz established a lupine "meadow," which has lasted to the present time, manured only with mineral manures. The soil was in 1880 analysed by Professor Maercker, side by side with soil kept under rye and potatoes for a like period of 15 years, manured with dung, and also side by side with soil uncultivated and unmanured during the same period used for pasturing sheep. The results were as follows :—

	15 years' permanent Lupine Culture.	15 years' alternate Rye and Potatoes.	15 years' unmanured (Sheep pasture).
	Nitrogen per cent. of Soil.	Nitrogen per cent. of Soil.	Nitrogen per cent. of Soil.
First depth of 8 in.	0·087	0·034	0·027
Second „ 16 „	0·025	0·011	0·021
	lb. per acre.	lb. per acre.	lb. per acre.
First depth of 8 in.	2,098	820	650
Second „ 16 „	1,368	602	1,150
Total nitrogen in the 24 inches ...	3,466	1,422	1,800

It will from this be seen that the nitrogen found, after 15 years' cultivation, in the soil and subsoil of the lupine "meadow" exceeded the mean of the other two plots by 1,855 lb. per acre. The quantity of nitrogen removed by the 15 years' crops of lupines is, however, estimated at 1,221 lb. per acre, so that despite the removal of more than half a ton of nitrogen in crops, nearly two-thirds *of a ton of nitrogen had accumulated in the soil* (as we now know from atmospheric sources) during the 15 years between 1865 and 1880.

A further analysis of the soil of the lupine "meadow" was made in 1891, eleven years afterwards, by Professor Holdefleiss, who found 0·177 per cent. or nearly *double* that which Professor Maercker had found in 1880, showing an *enormously increased accumulation of soil nitrogen.*

Apply "Observer Office,"
Colombo.

Continuous lupine cultivation for 25 years on a soil riginally poor and sandy aided only by *potash* and *phos-hates* not only, therefore, gave satisfactory crops, but—espite the exportation of nitrogen by yearly "mowing"—roduced *progressive nourishment of the soil itself*, thus con-lusively showing that, in the words of Dr. Schultz, "the ource from which plants can obtain their nitrogen is more bundant than was formerly believed. It is the part of man o utilise it more and more for the wants of agriculture, and he art of the farmer should be to endeavour better and etter to take advantage of it." To quote Mons. Grandeau. The *beautiful* researches of Hellriegel and Wilforth have evealed to us the true cause of this accumulation of itrogen by leguminosæ. It is for cultivators of the soil o turn it to profit more and more day by day, guided by he results acquired in the 40 years' experimental study of he eminent investigator at Lupitz."

The cultivation of a lupine "meadow" is, however, *not* eld up as an example of *practical* agriculture. The meadow" is regarded as an experimental or demonstra-ion plot. For practical purposes the system of Dr. Schultz s, as already said, based upon the *alternate culture of catch crops*," or green manuring. A catch crop improves he soil, not merely by the fixation and accumulation of tmospheric nitrogen in the soil, but by reason of the rganic and mineral matters which the crop leaves in the oil, and still further *mechanically* by the depth of penetra-ion of its roots. Catch crops, therefore, should be chosen vhich possess in the highest degree these three properties, itrogen accumulation, mineral accumulation in the roots, nd depth of root penetration. Nevertheless, mustard, rape, uckwheat, stubble turnips and other non-leguminous crops, ften used for catch cropping or green manuring, have a lefinite value in soils and situations suited to them.

Dr. Schultz experimented with some 30 leguminous crops, vith a view to deciding which was the most suitable for oil improvement. He tried 16 varieties of lupines, various inds of vetches and vetchlings, of peas and of beans. *He elects*, as being on the whole the *most suitable, lupines* yellow, blue or white), the hairy *vetch, kidney beans*, white *eas, Lathyrus sylvestris*, and *Lathyrus clymenum*.

The following table shows the total dry matter and itrogen contained per acre in a number of leguminous rops, taking into consideration both the plants above round and the roots, side by side being added a statement f the quantity of *commercial* nitrate of soda corresponding o the nitrogen indicated. It will be seen that if an acre f any of these crops be ploughed into the soil at the time f flowering—that being the time at which the determinations vere made—the *quantity of nitrogen contained in the green nanure* thus applied would be equal, on an average, to nearly *alf a ton of nitrate of soda.*

The effect would naturally not be the same as that of so arge a dressing of nitrate of soda, for it is of course to be remembered that green manure decomposes and yields its itrogen much more gradually than nitrate of soda, and is nore comparable to dung. It would be a better comparison, erhaps, to state that if ordinary dung be taken to contain ·5 to 0·8 per cent. of nitrogen, then the average leguminous reen crop ploughed in, as aforesaid, would contain as much itrogen as about 9 to 15 tons of dung per acre.

—	Total Dry Substaces.	Nitrogen.	Equivalent of Nitrogen expressed as Nitrate of Soda.
	lb. per acre.	lb. per acre.	lb. per acre.
Lathyrus clymenum ...	5,113	157	1,000
Peas	7,183	200	1,274
Mixture of Leguminosæ.	6,027	165	1,051
White Lupines	6,282	164	1,045
Blue „	7,053	172	1,095
Yellow „	5,077	129	821

Such alternate husbandry as constitutes the principle of the cultivation which has developed the Lupitz estate is carried out in various ways. The catch crop can either be sown immediately after the principal crop is harvested and the land ploughed up, or it may be sown with the principal, as has been long practised generally in the case of clover sown with or on a corn crop.

(*To be continued.*)

INFLUENCE OF BEES ON CROPS.

THERE is nothing more interesting in the life history of the vegetable kingdom than the methods and agencies of its reproduction. Fascinating as it is, it is too often the stumbling block of amateurs whose love of plant life carries them to look into the deeply-hidden mysteries of this absorbing subject. The sexuality known to exist in blossoms; their matrimonial instincts; their marriage ceremonies; their domestic ties; their methods of raising and perpetuating their families and co-relations; the officiating and conjugating priests, and the agreement between the contracting parties, are all more or less like fairy tales than actual facts.

These matrimonial ceremonies, how they marry and are given in marriage, is the portion of the subject I here wish to deal with. The arrangements of the sexual reproductive organs and their various functions have already been dealt with.

In the higher members of the plant world there is a very great difference between pollen cell and the ovule (little egg) that are joined to form new individuals. The former of these is smaller than the latter, and more active; it is the male; and the latter, of course, is larger than the former; is composed of richer matter, and is passive —it is the female. From the nature of these ovules, these passive eggs, they cannot become seed or plants until they are united with and fertilized by an active or live pollen again. The essential organs in blossoms known as anthers contain these active cells, the cells of life. The pistillate organs contain the passive cells, the cells of matter. The pistil in apples, pears, or other fruit blossoms is the bride, the stamens seen in blooms of like trees are bridegrooms, and the honey bee is the licensed officiating priest who is to perform the connubial ceremony. Let us for a while watch these officials of Nature carry out some of their highly important duties. Bearing in mind, whilst so watching, the table of kindred and affinity wherein it is stated a man may not marry his grandmother or a woman her grandfather, etc., and note how these insects, without a written law, are never parties to close or blood relations inter-marrying; neither does their natural instinct permit them to per-form unnatural alliances. They will not attempt to marry an orange to an apple, or a pea with a pumpkin, or pear with a cherry, and so on; neither does Nature permit them to marry the male of a blossom with a female of the same bloom. Such alliances in the higher plants are repugnant to all concerned. Nature's motto in the vegetable kingdom, as well as in the animals, is, especially when aided by the intelligent hand of man, "upward and onward." If the pollen of a blossom were transmitted to the carpels of the same, the result would be degradation, and the loss of some of the choicest varieties of fruit and vegetables we now raise from seed.

The ovary is composed of one or more carpels. The ovary of an apple bloom has five such carpels. In the mature fruit these are termed the core.

In the early spring mornings, when the bees issue forth to go in quest of stores, the first thing they gather is pollen. It is the first

product the blossom yields, even before it secretes its nectar (honey). In their eagerness to be first on the foraging ground, they leave home at about sunrise. If they have selected an orange to gather their stores from, they will keep upon orange or some other member of the citrus tribe during the whole of that peregrination. Tumbling about in the cup of the flower amongst the anthers, they gather up in their fur numberless grains of these life cells, pollen grains. Head, thorax, abdomen are all more or less dusted with it. Whilst gathering it, and whilst on the wing from flower to flower, and tree to tree, they are busily engaged in packing it in the pollen baskets that are situated in the upper part of the hinder legs. As the day warms, the blossoms unfurl; the central whorls develop, and the stigma becomes receptive. The bee, eager in her duties to supply her home with abundance of food, both for the young brood and winter storage, commences her search for honey. In the early morning there is little or no nectar secreted; but as the warmth increases, so the flow of honey advances. Anxious to fill her honey-sac whilst gathering the pollen, she enters the blossoms where she will find the greatest abundance of her favourite winter storage, and thrusts her tongue down into the nectries of the blooms. To get at the honey more readily she lies on the top of the essential organs, and brushes to and fro on the stigma. Whilst thus engaged, the fur on the various parts of her body retain pollen grain; those on her breast come in contact with the stigmas of the flowers. Having commenced working on an orange for pollen she will not go to an apple or aught else for her honey. Citrus fruits supplied the pollen, citrus fruits must provide the honey. Why? Because Nature has endowed the bee with that intelligence—there is no other word so applicable—to know if she were to take the pollen of an orange to the stigma of an apple, as far as fructification was concerned, her labour would be useless. Pollen from one species of the vegetable kingdom can seldom be used successfully, even by artificial means, to fertilize that of another species. When it is successful, the result is a hybrid, the descendants of which cannot be perpetuated by seed, but only by cuttings, grafting, etc. Bearing in mind the characteristics of the stigma, its adhesiveness, and its hairy hooklets, the bee's breast coming in contact with the latter, it acts as a comb or brush, and aids in detaching the pollen grains from the fur of the bee. These grains fall on the adhesive stigma, and are retained by its viscidity. When this contact takes place—sometimes at once, at other times it may be delayed for hours—the cell of life starts into activity by throwing out a pollen tube, which at once goes in search of the cell of matter contained in the passive ovule. To accomplish this, the pollen tube makes its way down the style which connects the stigma to the ovary. The silky threads that protrude from a cob of corn, delicate as they are, are not too fine or too long for these active tubes to penetrate. The style of the orange, etc., is also as easily pierced. The ovule, or young seed in the ovary, contains the embryo of the future plant. The pollen tube having found its way to the ovule, the union of the respective cells takes place. The ovule thus receiving the "germ of life," the infantile development of the future orange or other tree, as the case may be, commences.

When the contact of the two cells has been accomplished, the calyx withers; the corolla, with the dead remains of the stamens adhering thereto, falls to the ground; and the pistil in most cases is absorbed in the fruit.

These developments will be better understood by reference to a peach or other stone-fruit. When the ovule has thus been fertilized, the seed, or as it is generally termed the kernel, is the first to develop, followed by that of the hard shell surrounding it, the stone; and at the same time the flesh increases and matures with the gradual expansion of the outer skin. We then say it is ripe, *i.e.*, its flesh has become useful as food to man, and the seed capable of reproducing its species.

Now, it must be obvious to the most casual reader of these articles that the bee has played the imperative part in the production of these fruits. Nothing else would have accomplished it so effectively and with such beneficial results as the little busy bee. Other insects live on honey and pollen, but no other insect is endowed with the instincts of social bees. They work so systematically in cross pollenization. They make no mistakes. They will carry pollen from variety to variety, and sometimes from species to species, but not from order to order. After a foraging excursion they are never seen to return to the hive with different varieties of pollen on th bodies. In examining a cell of pollen in the hive, each stratum seen to belong to distinct species of the vegetable kingdom (r varieties). With other insects that only feed on pollen grains, th consume it on the anther whereon they alight. It is for immedi consumption for each one's present wants. Where other inse visit one blossom bees will visit a hundred. Watch a butterfly o flower and compare its actions with the rapid movements of a b and judge for yourself which is the better worker of the two. Y must bear in mind that in early spring flowers, and especial fruit blossoms, mature rapidly. Of the essential organs the anthe in most cases come to perfection first, and are the first to d The pollen is distributed in a very few hours, and its vitality in mo instances is short-lived. The pistil with stigma and its carpels a very delicate organisms, therefore liable to all kinds of acciden When we remember the chief characteristics of the stigma, it will seen that a dust storm is capable of clogging it, and thus preve fructification. A dust storm in early spring has a deal to answ for in the failure of fruit crops, so has heavy rain, wind, or anythi else that may bruise those very delicate portions of the flow From this will be seen the imperative necessity for some rapidl moving agent to convey the perishable pollen to the highly sensiti stigma. The numerical strength of these agents must be in pr portion to the quantity of work they have to do, or the areas und fruit culture they are expected to visit. If bee-keepers and the bees were banished from Australia there would be fruit, but i what quantities? I have referred elsewhere to the mischief done b butterflies and some other insects, but no such mischief ev follows in the wake of the bee. Fertilization by agents other tha bees would be sufficient to perpetuate species of fruits, and occ sionally to produce varieties, but to fertilize heavy crops sufficient feed mankind they are too inactive, and the mature insects numer cally too weak. If adult butterflies, etc., were equal in number adult bees, a famine would follow in the track of their larvæ disastrous as that caused by the armies of locusts that have bee known to sweep over the Holy Land in times past. Numerou insectivorous birds and other animals almost live exclusively o insects, their eggs and larvæ, and thus their injurious ravages a somewhat checked.

How wonderfully has Nature protected this invaluable insect- valuable not as a honey-storer, but as a fruit-producer. Practical the adult bee has no enemy, if we except the wood swallow, and the egg and larval stages its home is almost impregnable to inv ders. Of course, like the human family and other animals, it liable to the "ills that the flesh is heir to." In a state of Nature be ova and larva have one arch enemy—the bee moth—and it is well it should be so. Bees in a state of Nature are a great drawbac to bee-keepers. The honey, when obtained, is of a fourth-rate qualit owing to the quantity of foreign matter mixed through it. Tha same honey, if stored in the frames of the hives of practical be keepers, would be worth four times as much as when obtained bush-honey But this is a digression. To the careful bee-keepe enemies, not diseases, to the eggs, larva, and young bees are rarel known. The bee-keeper having his stock under control can, wit the greatest ease, regulate the supply and demand.

No district can be overstocked with bees, if we regard them fruit-fertilizers only, but as honey-gatherers it is another matte The greater number of bees kept in an orchard or fruit district, th more rapidly is fertilization carried on. Once the bee has carrie the pollen to the pistil, the act of fructification being successful, th development of the fruit is assured—the fruit has set. A few day after the bloom of the trees has disappeared the infant fruit can b seen in the early stages of growth. Standing near an apple, orang or other tree when the fruit is in its earliest stage, and a gent wind shakes the branches, you will sometimes hear the fruit fallin in hundreds, or if the tree is shaken the same results will follo In walking through an orchard in spring-time, young fruit jus formed are always seen in greater or less numbers scattered on th ground. The premature falling of these fruits is the result imperfect fertilization, caused either by slight injuries to the stigm or an insufficient number of bees to discharge the duties Natu requires of them, *i.e.*, fructification.—Albert Gale in *N. DISTRICT ASSOCIATIONS.

COORG.

Proceedings of a General Meeting of the Coorg Planters' Asso tion held on Friday, 25th February, at the Bamboo Club, Pollibet

Present.—Messrs. E. M. Breithaupt, G. Davies, W. Davies W. Finlayson, F. W Gerrard, J. Logan, F. Macrae, H. G. Meyn Jas. Rose, and H. G. Parsons, *Hony. Secretary.* Mr. John Logan the *Chair.*

The following gentlemen were unanimously elected members the Association :—

Mr. H. G. Meynell—*Proposed* by Mr. W. Davies and *Seconded* by Mr. Parsons.

Mr. A. N. Scott —*Proposed* by Mr. Parsons and *Seconded* by Mr. Logan.

The Hony. Secretary read a report of the deputation of Committee of the Association to the Chief Commissioner at Pollibe on the 17th January. The various subjects were discussed by Meeeting, and stress was laid on the point that if possible a co parative statement may be prepared of the surplus revenues Coorg as with that of other provinces, seeing that the Governm of India have under consideration the imposition of sundry lo taxes; the feeling being pronounced that a portion of the surp revenues might be justly relinquished.

U. P. A. S. I.—Various circulars read and recorded, and the nomination of the Hon'ble Mr. Hodgson as Member of Cou approved.

Treasury Drafts on Mercara.—

Read letter from the Accountant-General, dated 17th February which he said that if suitable to members of the Association would grant drafts for Rs. 1,000, but in doing so it might necessary to charge ¼ per cent. on all drafts from Rs.3,000 Rs.1,000.

Resolved that the thanks of the Association be conveyed to Accountant-General for his courtesy and that his proposal accepted.

AIL TONGA SERVICE.—

Read letter from Postmaster-General, dated 17th January, 1898, with reference to increased subsidy and change of route *viâ* Pollibetta.

Resolved that while this Association regretted it was not in a position to assist the Postmaster-General in the manner indicated, it was considered a progressive and convenient step to change the route *viâ* Pollibetta to Sidapur, and that the contractor was deserving of an increase to his subsidy if only in consideration of the change.

Read demi-official from Executive Engineer, *i.e.*, Pollibetta-Sidapur Road and Pollibetta Hospital.

The following papers were laid on the table :—

Shevaroy Planters' Association—for September, November, December, 97, and January, 1898.

Wynaad Planters' Association—for November, December, 1897, January d February, 1898.

Central Travancore Planters' Association—for October, 1897, and January, 98.

The Lower Pulneys Planters' Association—for October, 1897.

Nilgiri Planters' Association—for November, 1897.

Administration Report of the Coorg P. W. D.—for 1896-97.

Report on Public Instruction in Coorg to 1897.

Do. on Forest Administration in Coorg.

Do. on the Administration of Coorg.

nd with a vote of thanks to the Chair, the meeting closed.

H. G. PARSONS.
Honorary Secretary.

LOWER PULNEYS.

PROCEEDINGS of a General Meeting held at the Dindigul Club on aturday, the 12th February, 1898.

PRESENT :—Messrs. W. H. Gerrard (*Chairman*), G. Mengel, H. R. Newport, E. Morgan, H. O. Newport (*by proxy*), H. Ludwig (*by proxy*), . R. Gerrard (*Hon. Secy.*)

Read notice calling meeting.

Minutes of last meeting taken as read.

Read letter from Mr. C. P. N. Martin, dated 26th October, 1897, esigning membership of the Association as he is leaving the district.

1. Coffee Scale and Lady-birds.

Read letter from the Hon'ble Mr. H. P. Hodgson, dated 26th November, 1897, enquiring if Mr. H. O. Newport will go to Australia, nd if so, his terms.

Read Mr. H. O. Newport's letter, dated 6th December, 1897, in eply to the above.

Read letter from Secretary, U. P. A. S. I., dated 18th December, 897, to Mr. H. O. Newport, mentioning amount available to meet ost of importing Lady-birds, and asking him when he proposes to tart.

Read letter from the Hon'ble Mr. H. P. Hodgson, dated 24th December, 1897, enquiring what places Mr. Newport is likely to visit n Australia, &c.

Read Mr. H. O. Newport's letter, dated 31st December, 1897, to the Hon'ble Mr. H. P. Hodgson, in reply to the above.

Mr. F. R. Gerrard here said—

This was the last letter I received with reference to Mr. Newport's nomination, and was unaware what arrangements had been made, till I received Mr. Newport's Post Card, dated 23rd January, telling me that everything was settled, and that he was leaving for Australia on the 28th January, 1898, and after Mr. Newport's departure, I received his letter dated 27th January. (Letter read.) On receiving this letter I wrote on the 1st February to the Secretary, U.P.A.S.I., and Honorary Secretary, Nilgiri Planters' Association (letters read) and received from them the following replies :

Read letter from Secretary, U. P. A. S. I., dated 5th February, 1897.

Read letter from Honorary Secretary, N. P. A., dated 6th February, 1897.

This, Mr. Chairman and gentlemen, ends the correspondence that was passed in connection with Mr. Newport's mission to Australia to import Lady-birds.

After discussion in Committee,—

1. It was resolved that the Honorary Secretary write to Mr. Newport (*a*) That no consignments of Lady-birds be forwarded to India prior to Mr. Newport leaving Australia, but that he bring as large a consignment as possible with him. (*b*) The question of future consignments will be determined upon after Mr. Newport's report in India upon the success of the first consignment. He will, however, be requested to make all necessary arrangements, short of committing the Association to any expense or liability with regard to future consignments, so that if such be decided upon, they can be obtained upon such terms as arranged by Mr. Newport in Australia from Agents or persons willing to undertake the collection and forwarding of them to India. (*c*) The matter of Head-quarters in India will be decided upon after Mr. Newport's return to this country. This being the most affected district, it is very desirable that Mr. Newport's Head-quarters be in this district. Mr. Ramsay has put the Pillavally bungalow at Mr. Newport's disposal for this purpose. (*d*) That the sum collected for this business, including the contribution by Government, amounts to Rs.7,530. This sum must under no circumstances be exceeded, and is all that is available to cover every expense in regard to this business, of whatever nature. Rs.3,983 have already been spent, leaving a balance of Rs.3,547 available.

2. That a copy of the above resolutions be forwarded to the Honorary Secretary, Nilgiri Planters' Association, and he be informed "That as Mr. Newport's letter of the 6th December, 1897, in which he embodies the terms under which he would consent to proceed to Australia, and otherwise undertake the mission regarding Lady-birds and Green bug, having been forwarded to Mr. Hodgson, without comment, the terms have the consent of this Association, and this Association must now stand by them."

Mr. H. R. Newport put in a written statement taking exception to the last clause of the Honorary Secretary's letter to the Secretary, U. P. A. S. I., dated 1st February, 1898, which stated that Mr. H. O. Newport showed want of courtesy in not writing to the Honorary Secretary and Chairman of his Association regarding arrangements made for his trip to Australia before he left the district, and regretted that the Association should have made an accusation of the kind.

2. Roads and Communications.

Mr. F. R. Gerrard said—

On the 29th October, 1897, Mr. H. O. Newport and myself, on behalf of our Association, presented a petition to His Excellency the Governor, at Madura, praying Government to expedite matters in connection with the Ahtoor-Kodaikanal Ghat Road.

We hope Government in the coming official year will not forget the Madura district in making a grant towards the construction of this very important road.

The following is His Excellency's reply to our petition. *Address presented on 29th October*, 1897.

His Excellency, in replying, thanked them for the cordial welcome accorded to him, and assured them that he deeply sympathised with them in their wants. He was fully aware that both the Hon'ble Sir Henry Bliss and Mr. W. Hughes, who had an intimate knowledge of their wants, were much interested in their project of a ghat road to the Pulneys. His Excellency said that the subject had come up for consideration and careful enquiry had been made into the matter. He continued :—

"It appears from inquiries made that the line already laid out *viâ* Paniakkadu, Tandikkadu and Manalur to the foot of the hills opposite Atur will best fulfil the primary object of opening up the Lower Pulneys. The continuation of such a road to meet the made part of Law's ghat would be of little benefit to Kodaikanal, which will still derive its supplies chiefly from Periakulam. It is also considered that the improvement of the existing track by the construction of a new one from the foot of the hills to Atur is properly a work which the District Board can be expected to carry out. All that the Government can undertake under the present circumstances is to make the road between the village of Paniakkadu and the foot of the hills opposite to Atur. This road will be made at such a gradient that hereafter when the amount of traffic justifies it, it can be widened sufficiently for cart traffic. I may add that unfortunately in our present financial position it is not possible to promise you any immediate undertaking of the work, but when the estimates for the next financial year are under consideration, I will remember to bring it forward, and if it is possible then to grant the estimates for the purpose, I shall be very glad to do so, but I cannot make any positive promise. We really do not know what our financial position at that time may be. You must be perfectly well aware that the Government of India, and consequently the Government of Madras, is in considerable financial straits at the

present time, in consequence of the enormous expenditure we have had to incur on the relief of distress throughout the country, and the present heavy drain on the resources of the Empire owing to the wars that are proceeding on the frontier. And this is a matter which I very much deplore, inasmuch as it is evident to you and to me that it has the effect of retarding the development of works that are intended to promote the advancement of the country. You may rely upon my taking the very earliest opportunity of attending to this particular want of the Pulney Hills, which, as I told you, is fully recognised by Sir Henry Bliss and myself. I will just add a word to thank you for your kind welcome, and to say that I have had, in the course of my official career, a great deal of intercourse with planters in various parts of the Empire, and I have always taken a sympathetic and deep interest in their enterprise and work, far away from their native land. I hope to have the same feeling of interest and sympathy for the planters of the Lower Pulneys."

Read letter from the District Board Engineer, dated 22nd October, 1897, also his letter dated 20th December, 1897, stating that the question of connecting Ahtoor by a road to Sempatti will be considered by the District Board, when Government decides on constructing the road to Ahtoor.—*Recorded.*

3. Agricultural Chemist.

Read letter from the Secretary, U. P. A. S. I., dated 30th December; 1897, forwarding copy of letter from Mr. Drysdale Turner, offering his services as an Agricultural Chemist.

Mr. Mengel said—

That a great deal had been said and written on this subject, but very few District Associations seemed to take any interest in the matter, and unless all or most Associations were unanimous in supporting the scheme, it was no use our trying to discuss the subject.

The papers were recorded.

4. Ardaloor Post Office.

Proposed by Mr. F. R. Gerrard that the Postmaster-General, Madras, be asked to open a Branch Post office at Ardaloor.

Seconded by Mr. W. H. Gerrard, and *carried.*

5. Cattle trespass on the Siroomullays.

Mr. Morgan, in bringing his proposition forward, said—

Owners of cattle on the Siroomullays, and I dare say on the Lower Pulneys as well, allow some of their cattle to run wild, and it is impossible to catch and send them to a pound. These cattle do considerable damage to coffee estates and other cultivation, and their owners pay no attention to the constant complaints brought to them.

How are we to remedy this grievance? Unless the members of this Association petition our Collector or Sub-Collector stating the above facts.

The people of the Tinnevelly District suffered much by cattle trespass, and they repeatedly petitioned their Collector, and I am given to understand that the Collector, with the approval of the Board of Revenue, sanctioned the shooting of these cattle, after giving a month's due notice to the owners. In the Salem District a Deputy Collector (Mr. Singaravaloo Pillay) I am informed was petitioned to about cattle trespass, and he, I believe, referred the petition sent to him to his Collector, quoting the Tinnevelly Collector's orders.

What the Salem Collector has done in this matter is not known.

I therefore beg to propose that we petition our Collector or Sub-Collector to warn owners of cattle on the Pulneys and Siroomullays, giving them a month's notice to take proper steps to prevent their cattle trespassing, and to have proper men to herd their cattle, and if they own wild or semi-wild cattle to get rid of them the best way they can before the expiration of the time given, or permission will be given to shoot such cattle trespassing on private properties.

Mr. H. R. Newport, in seconding the proposition, gave his experience of cattle trespass on the Lower Pulneys.

It was resolved that the Honorary Secretary address the Collector on this subject and embody in his letter Mr. Newport's experience of cattle trespass.—*Carried.*

6. Railways.

Mr. F. R. Gerrard said—

At our last Annual General Meeting it was resolved that a petition be got up, and forwarded to the Chief Secretary to Government at an early date, urging the necessity of opening up the Branch Ra way between Dindigul and Palghat.

This matter has been attended to and a memorial signed by t leading Merchants, Landholders, Planters and others of the follo ing towns, *viz.*, Calicut, Palghat, Pollachi, Gumungalam, Pud Udamalpet, Pulni, Virupatchi, Pulakanooth, Cunnivady, Dindig Siroomullays, and Uppliamputtai will very shortly be forwarded His Excellency the Governor.

7. Mr. Quarme and Leaf-disease.

Read letter from Secretary, U.P.A.S.I., dated 19th November, 18

Read letter from Secretary, U.P.A.S.I., dated 13th December, 18

The Association confirms the opinion expressed by the Chairma U. P. A. S. I., *viz.*, that it should be left to individual Planters take up the system if they feel so inclined, and to make th arrangements direct with Mr. Quarme.

Mr. H. P. Hodgson as Planting Member of the Legislati Council and the Honorary Secretary's reply.—*Recorded.*

W. H. Gerrard (*Chairman*).
Fred. R. Gerrard (*Hon. Secy.*),
The Lower Pulneys Planters' Association,
Dindig

A LESSON FOR THE WEAK.

Do you see that locomotive engine standing on the side-trac Something has broken down about it. There is not a hiss of stea from its valves; it is still and cold as a dead whale on a beach: can't draw a train; it can't even move itself. Now, tell me, do y believe that any amount of tinkering and hammering at it wou make it go? Not a bit. Nothing on earth will make it go exce steam in the boiler, and even that won't unless the engine is in ord Everybody knows that, you say. Do they? Then why don't th act on this principle in every case where it applies?

Here is such a case. Writing concerning his wife, a gentlem says: "In the autumn of 1880 my wife fell into a low, despondi state through family bereavement. Her appetite was poor, and food, however light, agreed with her. After eating she had pain a tightness at the chest, and a sense of fulness as if swollen around t waist. She was much troubled with flatulence, and had pain at t heart and palpitation. At times she was so prostrated that she w confined to her room for days together, and had barely strength move.

"At first she consulted a doctor at Ferry Hill, but getting wor she went to see a physician at Newcastle. The latter gave him so relief, but still *she did not get her strength up;* and after being unc his treatment for six months she discontinued going to him. Bet and worse, she continued to suffer for over a year, when she hea of Mother Seigel's Curative Syrup. She began taking it, and so her appetite revived and *her food gave her strength.* In a short ti she was quite a new woman. Since that time (now nearly twe years ago) I have always kept this medicine in the house, and if a of my family ail anything a few doses puts us right.—Yours tru (Signed) George Walker, Grocer, &c., Ferry Hill, near Durha October 25th, 1893."

We call attention especially to those words in Mr. Walker's let which are printed in italics. You can pick them out at a glan They show how fully he understands where human strength com from—that it comes from digested food and not from any medici the doctor or any one else can give us. Let us have no mistake confusion of mind on this important point.

For example, Mrs. Walker was ill with indigestion and dyspeps Her symptoms, and how she suffered, her husband tells us. T disease destroyed her power to obtain any strength from food, a Nature suspended her appetite in order that she might not ma bad worse by eating what could only ferment in the stomach and her blood with the resulting poisons. The only outcome of such state of things *must* be pain and weakness—weakness which, co tinued long enough, *must* end in absolute prostration and certa death.

Well, then, she failed to get up her strength under the treatme of either doctor. Why? Simply because the medicines they ga her—whatever they may have been—did not cure the torpid a inflamed stomach. If they *had* cured it then she would have got her strength exactly as she afterwards did when she took Seige Syrup. But the trouble is this: Medicines that will do this are ra

the doctors possess them they would use them, and cure people th them, of course. Mother Seigel's is one of these rare and fective medicines. If there is another as good the public has not t been made acquainted with the fact. But even the Syrup does t impart strength; it is not a so-called "tonic;" there is no such ing. It (the Syrup) *cures the disease,* drives out the poison, pairs the machine.

Then comes the appetite (all of itself) and digestion *and strength.* ou see the order—the sequence. Yes. Well, please bear it in ind. The mechanics set the engine in order; then the stoker gets the steam.

And of the human body—the noblest of all machines—Mother eigel's Syrup is the skilled mechanic.

MARKET REPORT.

COFFEE.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for e Week ending April 6th, 1898, says:—Bank rate 3%. Bombay xchange closes at 1s $3\frac{7}{32}$d. Brazil Exchange 6d. Rupee paper %. $62\frac{1}{4}$. Silver 26d per oz.

Supplies at auction have again been heavy, but the tone throughout the eek has been rather firmer, and the bulk has been sold at irregular ices. The better qualities of Costa Rica were well competed for, whilst dinary and medium show a reduction of 1s to 2s per cwt. Brazil arkets have been rather firmer, and close steady.

The Dutch Sale of 19,445 bales Java, 58 cases Padang, and 1,500 bales enado held in Amsterdam yesterday went off irregularly at lower prices, od ordinary selling at 33 cents, against 35 cents at the March sale.

Daily receipts averaged 10,000 bags in Rio and 3,600 bags in Santos.

Futures have ruled steady to dearer, showing about 1s per cwt. advance, z.:—Good average Santos in Havre, May delivery, fcs. 36, in Hamburg . $29\frac{1}{2}$, and No. 7 low ordinary Rio in New York $5.75.

UBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, t Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including age. Single Copies, Eight Annas.

DVERTISEMENTS.—From the 1st October, 1897, the charge for advertisements will be: 4 as. per line for the first, 3 as. for the second, 2 as. for the third and succeeding insertions. Five-line advertisements Subscribers will be inserted for three issues for one rupee; non-Subbers will be charged two rupees.

OMESTIC OCCURRENCE.—The fee for inserting a domestic rrence will be *One Rupee* for each insertion, payable in advance.

.B.—Remittances should be sent to the Manager, "Planting Opinion," anade Row, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been oved to Madras, all remittances should be made pay- e to the Manager of *Planting Opinion*, 11 and 12, cond Line Beach, Madras, who will also attend to all vertisements, &c.

Letters to the Editor should be addressed to Coonoor, usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 13th May, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Upper India. Generally speaking, the tea season has opened fairly well, and many gardens are slightly ahead of last year's outturn.

Coorg. POLLIBETTA, *5th May.—Weather.*—Rain has been falling nearly every day since last report, mostly of evenings and during the night. All thunder-showers from N. E. *Crops.*—Conditions favourable to blossom which came out on 26th and 27th ultimo. Some rain on blossom which came out on 30th ultimo. *Labour.*—Sufficient for the time of year. *General Health.*—Good.

Nelliampathy. *4th May.—Weather.*—Rain fell at last on several days between 19th and 28th of last month; in some places more than 7 inches were measured, while here I got only 2 inches. *Crops.*—Blossom has been out, and a marvellously good one for the most part it was, and every one is pleased, as crops ought to be up to the average this year. I fear most of the first blossom (February) has gone, seeing it had to hurry on for two months without a drop of rain. Coffee looking very well everywhere. *General Health.*—Lots of fever going.

Nilgiris. KIL KOTAGIRI, *29th April.—Weather.*—All that could be desired for the blossom; if the rain keeps off by to-morrow, all blossom will be set, I think. Some came out on Monday; the rest has been coming forward since. Most of the estates promise well this year, but none as

well as the two estates belonging to the N. P. Co. One estate of about 125 acres bearing coffee looks as if it would give well over 40 tons. We had no heavy rain this last burst that came on the 21st and brought out our blossom. *Labour.*—Too plentiful; coolies are flocking up, and more maistries came this year than ever known before. Last year's labour dismissed. *Health.*—Very bad. Fever prevalent. There are more coolies down now than usual at this time of the year.

Coonoor, *5th May—Weather.*—Not much rain since last report. The coming of the "chota bursat," which only means very strong wind and cloudy skies to us here, seems to be accomplished. *Crops.*—There has been a very nice blossom indeed, out on most estates, and everything looks favourable. Tea, I'm sorry to say, is decidedly in a poor way, but will probably make up lee-way after the south-west winds are over. *Labour.*—Plentiful. *Health.*—Indifferent.

Nellakotta, *3rd May.—Weather.*—Since my last report, dated 19th April, I have gauged on 20th April 7 cents, 22nd April 27 cents, 23rd April 44 cents, 27th April 25 cents, 30th April 30 cents, and 30 cents last night. We have had quite enough rain for the present. *Crops.*—Blossom was out on the majority of totes about the middle and end of last week. On all estates I have seen it was simply superb, and as it appears to have set nicely, we ought to have an exceedingly good season. But there are so many slips 'twixt the cup and the lip (the planter's I mean) that I won't prophesy. All I will say is that conditions could not be more favourable for a rattling good crop. *Interesting Items.*—Your Coonoor correspondent, I see, wants some one to start a subject for discussion during the slack season. Let me suggest that he should exercise his ingenuity in solving a riddle lately propounded in *Planting Opinion.* Why do the spring showers kill young plants wholesale? Is it because, after a long period of drought and consequently of rest, the early rains force the young plants to make a sudden effort beyond their strength?

THE CURRENCY SCHEME.

The names of members of Lord George Hamilton's Currency Committee were announced a few days ago. Scarcely had these been published when information reached us as to the general suggestions of the U.P.A.S.I., particulars of which will be found in the U.P.A.S.I. section of our present issue. Again, this had not been fully set in type before an announcement appeared as to the proposals which the Government of India had submitted to the Secretary of State for consideration. It is evident, therefore, that there is at last a prospect of some progress being made; but it is equally clear that the lines marked out by the Government of India are by no means those that the U.P.A.S.I. would wish to see followed. Government's scheme is not a very complex one. It aims at obtaining a reserve of gold coin by borrowing in England. British credit is to be turned to account. It is proposed that Parliament should empower the Secretary of State for India to borrow up to £20,000,000. This is to be kept quite separate from the usual borrowings of the India Office. The money is to be shipped to India and placed in the Reserve Treasuries. According to the Government of India's despatch, "the first use to which this gold would be put would be to supply the deficiency in balances caused by the sale of silver. Government reckons that its sale of ten crores of coined rupees would return to the treasuries only Rx.6,000,000, and the balance of Rx.4,000,000 would have to be made up out of the gold in hand, and would absorb about £2,700,000 of The result of the first year's operations would therefore omitting altogether any effect it might have in diverti gold towards India in the ordinary course of commerce (t is under conditions the same as those now existing) t Rx.6,000,000 of the existing rupee currency would be tak out of public use and paid over into our treasuries, inste of being returned into circulation in payment to import of silver, and that a further sum of Rx.4,000,000 wo cease to exist as coin forming portion of our balanc being replaced therein by Rx.2,700,000 held in gol To make its intentions still more clear, the Governm proceeds to consider the result of a similar operat during the second year. It remarks: "Suppose operation be repeated a second year, the amount of curr circulation available for trade purposes would be reduc by Rs.12,000,000, and the amount of coined rupees in possession changed into the form of gold would £5,300,000, giving a total reduction of silver rupee curren of twenty crores. Certain considerations stated are regard as indicating that before this point is reached the exchan rate would have attained a level of sixteen pence, or ev higher, and sovereigns would have flowed into the coun to fill up the deficiency in the current circulation outsi our own balances caused by the withdrawal of silver coi

From this we gather that 1*s.* 4*d.* is still the level t Government favours, and that its endeavours, at least first, are to be directed towards nailing the rupee at ab that level. When this has been done, the sovereign w says the despatch, "be a recognised coin of the Empire use, in its chief cities at least, and, as long as this condit can be maintained, exchange will be stable at about 16 Government claims that it will always have the pow "to carry the operation even farther by withdrawing a s larger quantity of silver and replacing it by gold coin, a it recognises that circumstances may arise in which su measure may be forced upon it; but the present intent is rather to trust to automatic operations of trade." observes: "The amount of coin required for the needs commerce increases every year. When any one ye permits of no increase in the amount of silver coin, we m reasonably expect that the effect of the increasing dema for coin will be to raise exchange to a point at which go will flow into the country and remain in circulatio The position will thus become stronger and stronger time goes on." Until this stage is reached Governme will part with none of the gold in its possession. Her the new scheme may be defined as having for its object t establishment of a gold standard with a view to t ultimate introduction of a gold currency.

Many arguments might be urged against the schem but there is also a great deal to be said in its suppo The evils of a varying rupee have been experienced for ma years. They have resulted in a dangerous tightness money, the practical effect of British distrust in the rup When that coin fell lower and lower in gold-value, it dam aged trade and seriously affected the Government's fina cial position. When it began to rise again, the planti community felt that their time to suffer had come ov again. It will be seen from the remarks made in t U.P.A. section that Mr. Romilly has come to the conclusi that nothing better than a compromise with other int ests can be hoped for. Government obviously consid

at a compromise will be arranged if the rupee be fixed at 4*d*. It follows, therefore, that prospects of getting a lower vel agreed to are not very bright. The Secretary of State proves of the objects of the scheme, and the Currency mmittee will have to consider whether these objects can st be attained by that scheme, or otherwise. It will be most interesting and difficult question to solve, and we ust that the planting community will be able to put rward strong and capable witnesses so that there may no room left for subsequent doubts as to whether the tter was fully represented from the planter's standpoint. they can get the Government of India's scheme rejected favour of a policy of reopening the mints, or if they can en get a lower level than 1*s*. 4*d*. agreed to, they will hieve a great victory.

BEE-KEEPING ON PLANTATIONS.

More than once has the matter of bee-keeping been ought to the attention of the readers of these columns being particularly suitable to plantation life. To its st possible economic importance to Indian planters we nfess we have not paid sufficient attention; this has en left to a resident of the West Indies, Mr. W. K. orrison, whose letter on the subject will be found elsehere. In view of the scant attention that has been given our indigenous bees and the paucity of attempts at mestication, it is remarkable to find that Californian e-keepers are anxious to introduce some of the Indian ecies to America. As Mr. Morrison remarks, it would greatly to the advantage of future Indian apiculturists r experiments to be carried out with our indigenous bee America. All modern hives with their ingenious pliances and fittings are based on the most accurate easurements of the architecture of *Apis mellifica*, the uropean or Italian bee. A smaller or larger size of bee ould necessitate the manufacture of different-sized hives d fittings, and it is very certain that such work could t possibly be done in India. True, apiculture may be rsued in the old-fashioned way, but this would involve very large loss in the yield of honey. To manufacture e pound of comb-wax, bees must consume many times at amount of honey, and thus it is that artificial combs ve largely replaced the natural insect-made ones. There e also many other and extremely ingenious appliances hich materially lessen the cost of production, and to spense with which would greatly handicap Indian iculturists.

It is clear, therefore, that if bee-keeping in this country ever to take the important place it should hold, American genuity must be availed of. In the A. I. Root Company, edina, Ohio, U.S.A., we have a powerful apicultural ganisation willing to further this matter of introducing dian bees into the Southern States. Not of course out sheer philanthropy, but from the more effective feeling self-interest. For, as we have remarked before, merican bee-keepers, or bee-masters as they call themlves, are very keen on experimenting with Indian bees, ore especially the *Apis dorsata* variety. To meet the mericans half-way, the work of collecting the desired rieties should be borne on this side, while the cost of rwarding would probably be entirely defrayed by the A. I. Root Company. Such a matter of course cannot be expected to develop spontaneously. Those interested in the matter should place themselves in direct communication with the firm mentioned, and ascertain exactly what is required, while on our side we shall of course be very glad to publish any information on the subject placed at our disposal.

Some of our readers may be wondering why we have omitted all mention of the advisability of introducing the European or so-called Italian bee to India instead of undertaking such purely experimental work as the Yankee managed business of domesticating the wild Indian bee. We would remind these that experiments with the Italian bee have, for many years past, been carried on in India—the most notable ones were located on the Nilgiris—with a uniform want of success. Further, that special and exotic honey-flowers are a necessity to the Italian bee, while the indigenous bee can take very good care of itself by gathering the nectar of the flowering shrubs of the country.

The production of honey from India Mr. Morrison puts, in a private letter to us, at one million tons per annum, a prodigious amount that, if realised, would utterly swamp the markets of the world. The planter has many points in his favour: he has a profession that gives him a good deal of time to devote to such a bye-industry as apiculture. Cheap labour in abundance is at his command, and for a market he has his choice between London and the teeming millions of the land. Were the American experiments to be successful—and there seems no valid reason why they should not so be—apiculture on plantations would soon prove an important rival to the culture of the staple itself. Many individual bee masters are in receipt of very handsome incomes, too, incomes derived from the application of a comparatively tiny capital. In some cases as many as 75 tons yearly are produced on single "farms," and when we remember that the wholesale prices of honey are not much under those of plantation coffee, the possibilities of bee-keeping may be appreciated.

NOTES.

Chloroforming plants. It is said that a chemist of Bavaria has prepared a fluid that has the power, when injected into the tissue of a plant, near its roots, of anæsthetising the plant—not destroying it, but temporarily suspending its vitality. If this process is found to answer practically as well as it does experimentally, the discovery will prove of immense importance to planters and horticulturists generally.

The Colombo market. It is very encouraging to note the strength of the Colombo market, especially at this period of stress in the tea trade. Local papers state that prices were (and perhaps still are) fully 1*d*. to 1*d*. ½ above London rates, owing to the strong and continued demand for Russian and Australian markets. The greatest danger seems to lie in a scarcity of freight, but as such a large proportion of Colombo sold tea does not go to London, not much difficulty is really likely to be experienced.

Japanese tea and the Russian market.

The St. Petersburg *Viedomosti* reports, says the *H. and C. Mail*, that a regular communication by steamers will be established next year between the ports of the Black Sea and Yokohama. The chief aim of the promoters of this service will be the export of Russian petroleum to Japan, and in exchange for this commodity raw iron and camphor are to be brought back. The Japanese Ministry of Trade has lately sent one of its officials to Russia with a view to finding openings for Japanese goods in that country. The producers of tea in Japan intend to introduce their tea into Russia, and to that end the first depôts for the sale of Japanese tea in Russia will shortly be opened in Moscow, Warsaw, and Odessa. An important Company has been formed in Japan to carry out the project.

The Indian Currency Committee.

We give below the names of the members of the Currency Committee; the "terms of instruction" are as follows :—

"'It will be the duty of the Committee to examine the proposals of the Indian Government, and any other matter which is strictly relevant thereto, including the probable effect of any of the proposed changes in the monetary system upon the internal trade of India and upon taxation, and to submit any suggestions which it may think advisable for establishing a satisfactory currency system and securing a stable exchange.' The last sentence would seem by its own terms to preclude any possibility of open mints, even if the Committee were in favour of them. But, inasmuch as it is reported that the City generally is distinctly averse to the gold reserve scheme, a return to open mints is by no means an utter impossibility. As was expected, Sir Henry Fowler is to be the Chairman, and a better Chairman could hardly have been selected. The members are Lord Balfour of Burleigh, Secretary for Scotland, who is said to be the probable successor of Lord Elgin; Sir John Muir, of Messrs. Finlay, Muir & Co., Calcutta, who presumably represents planting interests; Sir Francis Mowatt, Permanent Secretary at the Treasury; Sir David Barbour, formerly Finance Minister in India; Sir Charles Crosthwaite, Member of the India Council; Sir Alfred Dent, a China Merchant and Founder of the North Borneo Company; Mr. F. C. Lamarchant; Mr. Hambro; Mr. Holland, President of the Manchester Chamber of Commerce; and Mr. Robert Campbell, Chief Manager, National Bank of India. The Secretary is Mr. Robert Chalmers, of the Treasury."

Tea-cess on Indian tea.

It has been felt with yearly increasing force that the funds now provided by Indian tea-planters for the exploitation of new markets are a great deal too small to effect their purpose. It has been several times proposed that Government be approached on the subject of levying an export cess on all tea shipped from India in the very successful Ceylon fashion. From one reason and another, however, the matter h never been pressed home. The latest suggestion is the effect that an attempt should be made to put in practice, voluntarily, the proposal for a tax on every pou of tea sold. This could be done by an unanimous agr ment being arrived at to instruct the Selling Brokers deduct a certain rate per pound or a certain percentage, might be agreed upon, from all garden invoices passi through their hands. The Brokers to collect the proce and pay it to the Association. It was estimated that charge of half pie per pound on 120 million lb. wo realize about three lakhs of rupees, or three times as mu as was now collected under the voluntary levy.

The General Committee of the Indian Tea Associat are of opinion that the suggestion is worthy of care consideration, as apparently providing a very easy a practicable mode of raising a larger sum of money, and was decided to pass it on to the Association in London their opinion, stating at the same time that the Gene Committee on this side were inclined to view the propo with favour.

Export of bones from India.

Our contemporary, *Indian G dening*, will by no means admit th Dr. Leather was correct in his findi that Indian soils did not, as a rule, need phosphatic manur In a vigorous leaderette he says :—

"In a recent issue of *Capital* there appeared an article on t subject which is calculated to convey the idea that bones are of manurial value. The writer says : 'Bones have failed *with their ph phates* to make up for the *deficiency of phosphates* in Indian soi This will strike the intelligent reader as a contradiction in ter To admit the 'deficiency of phosphates in Indian soils,' and argue that a substance *having* phosphates has failed to make that deficiency, is surely curious logic. Phosphatic manures hav very high value in the case of certain crops, notably indigo. But argue that because 'the experiments conducted at the vari Government farms with phosphatic manures have not produced effects which they were capable of,' and that therefore bones ar no manurial value, seems to us to be based upon wrong premis We have before us the report on the Cawnpore Experimental Fa for season 1896-97, wherein is a statement showing the results tained in the cultivation of the country potato. Here we find t the unmanured plot gave a higher outturn per acre than any of manured plots. It would be very unsafe to argue from this t manures in general are of no value for potatoes. It has been dem strated by the Chief of the Division of Chemistry in the Uni States Department of Agriculture that potatoes contain about parts per thousand of potash salts; therefore, the most suita manures for potatoes would appear to be such as contain a la proportion of potash. To ascertain the exact value of any man for a particular crop, it seems to us that the point to settle is proportion of the various chemical constituents each crop remo from the soil. This once ascertained, it would be a comparativ easy matter to determine the particular kind of manure suitable any particular crop. To carry out such analyses of soils, it wo be necessary to have the services of a properly qualified Agricultu Chemist. To make rash statements regarding the worthlessnes any particular manurial product without having obtained facts b ing on the point is not a satisfactory method of disposing of question. Every gardener knows the value of bone-meal a fertilizer for even flowering plants, while for fruit trees, as a r bone-meal is a most important manure. We disproved Dr. Leath conclusions as to the value of bones in our issue of 30th Septem 1897, and we maintain that the export of bones from India certainly calculated to deprive the country of a most valuable con tuent of the soil."

Indian Teas.—With an improved demand prices generally re firmer. The next public sale will not be held until onday week. The finer descriptions have again been ctively competed for, and owing to the comparatively small pply to come forward it is quite probable the highest point r really fine tea has not been reached. At this period of e year there is generally a considerable shrinkage in the pply of the better class teas, but it promises to be more ronounced than usual this year, as nearly all the produce the principal gardens is disposed of. For all useful edium sorts there has been a fairly active demand. After aster, when a more general enquiry may be expected, a tronger market is anticipated, as the bulk of the future pplies will no doubt consist of the commoner kinds. As the tock of the latter is now very considerable, the prospects are kely to be more favourable to the buyer than otherwise, specially for the thin liquoring teas, as similar grades of eylon are coming forward freely. The figures are more atisfactory for the past month than for some time, as he following will show:—Imports 6,688,000 lb. against ,059,000 lb. in March last year, while the deliveries are pwards of 500,000 lb. more, or 11,717,000 lb. and 1,194,000 lb. respectively; and the increase in the stock as been reduced by nearly 1,000,000 lb. compared with ebruary, the quantity now being 59,051,000 lb. against 1,289,000 lb. There were 18,763 packages catalogued for ublic sale on Monday, 1,790 of which were withdrawn, and rom now until the end of July the sales will only be held n the Monday in each week.

LETTERS TO THE EDITOR.

BEE-KEEPING FOR PLANTERS.

SIR,—By the last number of *Planting Opinion* I see that experiments with *Apis mellifica* in the Nilgiris have failed, but no reasons are given for the failure. I have written somewhat on this subject for our bee journals, so that this matter greatly interests me. Cannot some one write a synopsis of the experiments thus far? It would be very interesting to the bee masters of the world. I am, however, of the opinion that some of your native races (or species) of bees would prove excellent honey-gatherers, as you suggest in the article under consideration. It would be a difficult matter, however, for an amateur to handle such experiments. A larger or a smaller bee than *Apis mellifica* will require an entirely different hive, for all the measurements of the modern movable frame hive would have to be changed—no small change surely, for modern hives are based entirely on accurate measurements of bee architecture.

The bee-keepers of America are anxious to try the bees of the Indian species, so why couldn't this matter be arranged to work for the ultimate benefit of both Indian and American planters? There are 500,000 bee-keepers in America. How many in India? This is entirely a practical question. The Editor recommends the ladies to try bee-keeping. I would rather recommend the planters to try it, for it requires both energy and hard work to make a success of this business; in fact, the same management that is required for a tea plantation is required for bee-keeping If your planters are really anxious to get hold of a paying industry, here is one that promises very well and which dovetails with the planting interest. It will only take a small sum of money to try it experimentally.

DEVONSHIRE, BERMUDA ISLANDS, *April* 27, 1898. W. K. MORRISON.

GENERAL ARTICLES.

THE U.P.A.S.I. SECTION.

(UNDER THE CONTROL OF THE SECRETARY, U.P.A.S.I.)

THE endeavour to arrange for the Planter's 'case' in regard to the Currency question to be put before the Currency Committee, has achieved some success. The name of Mr. G. L. Acworth, ex-Chairman of the U.P.A.S.I., has been placed before the Secretary of State by the Government of India, and there is very little doubt that Mr. Acworth will be allowed to, and will, give evidence. Besides this, the Hon'ble Mr. Hodgson, the "Planting Member," leaves for England this month, and it is hoped that he will be in time to obtain a hearing. Again, the names of those planters who are known to be in England just now have been transmitted to Mr. Acworth, who has been requested to call at the India Office and make all arrangements that may be necessary to have all, or at any rate some, of these gentlemen invited to give evidence before the Committee. It seems fairly certain, therefore, that planters will have a fair opportunity of giving expression to their views.

What those views are can scarcely be stated, for

FOR SALE.—Hand Camera ($\frac{1}{4}$ plate) by Robinson, Dublin, in first-class condition with 12 slides for plates—also some $2\frac{1}{2}$ dozen plates (more or less), 6 developing dishes, 3 optimus printing frames, and large assortment of photographic chemicals. Price on estate Rs.75. No offers. Apply—M. W. LITTON, Shaniwarsanté, N. Coorg.

allowance must be made for differences or variations of opinion on points of minor importance. The broad arguments that are likely to be pressed upon the notice of the Committee are those contained in the U.P.A.S.I. circular on the subject, issued about three months ago. As, however, it is very improbable that the Currency Committee will fall in with the suggestions therein made with respect to the reopening of the mints and the levy of an export duty, there is some prospect of planters agreeing to, or perhaps even suggesting, a compromise. In fact, the Chairman of the U.P.A.S.I., while pointing out to Mr. Acworth that an export duty in India would need to be accompanied by an export duty in Ceylon, has suggested to that gentleman (1st) to visit Mr. Christie and arrange to work in unison with Ceylon as far as possible; (2nd) to work in with any representative of Northern India who can be found; (3rd) to take the U.P.A. circular as his basis; and (4th) if he finds that the fixing of the rupee at a certain gold-value is insisted upon, to get that value fixed as low as possible.

Mr. Acworth is given a free hand, but suggestions have been made to him as to the line of argument the Association would wish him to pursue. It is probable that no amount of evidence or even proof that the mints ought to be reopened would carry weight with the authorities, as Government is committed to an entirely different policy, and is likely to have the support of a strong body of merchants and others whose desire is to have a stable exchange. As this party is almost certain to win, the most that planters can hope for is a reasonable compromise. Hence the suggestion to Mr. Acworth that if the decision of the Committee is that attempts to give a fixed value to the rupee ought to be continued, he should direct his aim mainly towards getting the level fixed *as low as possible.* The competition of China, Japan and the Straits is, to all intents and purposes, a bounty-fed competition, and planters must try to protect themselves against anything of this kind, even if they fail to convince Government of the desirability of giving India "honest money."

NITRATES versus NITROGEN.

Practical Hints to Planters.

In a recent issue we wrote at length on the great practical importance of the nitrate-forming bacteria to the planter. Granted favourably conditions of soil, temperature (95° to 100° F. is supposed to be best), moisture and aeration, our tiny friends can supply our crops with all, and m than the nitrogen they require. Over the actual clima changes that influence the state of the soil so largely we course, have no control. But, on the other hand, it perfectly feasible, by means of intelligent cultivation, modify the effects of the weather in almost any directi required. This question, as Mr. A. Baur, of the Cey Manuring Works, points out to the public, is not one theoretical importance alone: it is of vital practical inter to all interested in agriculture. It is a significant fact th the leaders of present-day scientific cultivation in Southe India lay much stress on the efficient cultivation of t soil, as well as on the very expensive chemical manu they use so freely. Bearing in mind the great costlin of up-to-date cultivation of coffee, for instance, running to three hundred rupees per acre annually, it is surely idle question to investigate whether a large portion at le of the cost of the chemical manures might not be avoid For at present there is no doubt that manuring claims t first attention of all planters.

With our present system of cultivation great bacter activity is only present for certain very limited periods the year. It should be the aim of the planter to prolo this favourable season as much as possible. Putting on o side the conservation of bacteria-charged soil under artific conditions, a great deal can be done in the field itself. very dry weather the growth of bacteria is arrested, a more especially in the case of tea plant growth is noticeab and simultaneously checked. This is not due to the actu want of water to the plant roots, but to want of the fo ordinarily produced by the bacteria. And it is just at th period that most water is used up by the plant in endea ouring to make what growth it can. It is in this wa Every pound of plant issue formed by the plant is ma from a definite quantity of nitrogenous and mineral elemen present in the soil. This food is drawn up as "soup." good and rich soil, this "soup" is highly concentrate and consequently the proportion of water used per pou of plant tissue is very much less than in poor soil. F in poor soil the "soup" is very diluted, and compar tively huge quantities of water must be used befo the proper amount of food is drawn up. Soil, otherwi rightly considered as rich and fertile, may, by a prolonge drought, be rendered sterile for the time being by the wo of the bacteria being interrupted. Crude nitrogen is no use to the plant, as until converted by bacteria in nitrates the plant roots cannot take it up. It is obvio here that deep and thorough cultivation would, by increasi the water-holding powers of the soil, do much to obvia the ill-effects of the drought.

On the other hand, excess of moisture is just as fatal the well-being of bacteria as excessive drought itse Other things being equal, and paradoxical though it ma seem, deep cultivation will likewise go far to correct th evils of superfluous moisture. For, instead of lodging a comparatively small quantity of soil, the rain will soa through the porous surface and drain away into the subso

General rules cannot, of course, be laid down as equall applicable for such diverse crops as coffee and tea, no should any given system be adopted indifferently on a soils. Clay soils, for instance, should be treated in quite different manner to light soils, and soils rich in humus soils deficient in that constituent. Coffee requires certa

efinite periods of rest, such as the wintering previous to lossoming. Tea, on the other hand, is in no such need pparently, and growth all through the year should be stered as diligently as possible. Shade, by the way, favours trification, as also do abundance of mineral manures and certain quantity of organic débris.

To pursue this subject further would be to enter on a mplete disquisition on the cultivation of tea and coffee, hich would be quite foreign to our purpose. We have tempted in the above to arouse a practical interest in the mmonplaces of modern agricultural science, and trust we ave partially succeeded.

HINTS ON USING LIME.

Prof. Person, U.S.A., gives some valuable hints on this bject :—

"When soils are of an acid character, such crops as clover, alfalfa, cerne and certain other leguminous plants which under proper soil nditions have the power to utilize the nitrogen of the air existing in e soil are unable to make a satisfactory growth. Moderate applitions of water-slaked lime under such circumstances will prove ghly beneficial in sweetening such soils and promoting nitrification. ften injury results from the application of lime in a caustic state. hen applied in this form, particular care must be exercised to void excessive applications, even on soils where crops requiring a latively large lime nourishment are to be grown. Next to the ater-slaked, air-slaked lime is the most satisfactory form in which make lime applications. On thin, sandy soils deficient in lime, om 500 to 1,000 pounds per acre is the proper quantity to apply. n heavy soils these quantities should be increased about one-half. is generally best to make lime applications sometime in advance planting. Autumn applications are generally to be preferred. should be distributed with great uniformity and carefully plowed nd harrowed into the soil, otherwise its beneficial effects will be reatly retarded. On soils needing this material, about every four ears would be the proper interval for administering lime dressings soils. Lime should immediately after being applied be harrowed to the soil, otherwise it will likely cake, and this would detract om its good effects.

"It is a very easy matter to ascertain whether or not a soil ssesses acid properties. Soils that contain much carbonate of me are of an alkaline character (*i.e.*, directly opposite to acid). ch soils, of course, need no liming. But when a soil is disctly acid, as is often the case, particularly when muck soils, lditions of lime are always desirable. In order to determine acidity, very simple test will suffice. Employ a narrow strip of blue tmus paper, an inch and-a-half in length (to be had for a trifle at y apothecary shop) in conducting the test. A few ounces of the spected soil may be placed in a glass and made into paste with ater by stirring with a rod or stick. Allow the paste to stand for half-hour, and then with a knife blade separate the paste, and sert the strip of litmus paper and press the moist soil against it ith the blade, and allow the paper to remain in this position for out five minutes. Remove the paper and see if the end placed in e soil has changed from the original blue colour to red. If such a ange has occurred, it proves that the soil is acid, and that an plication of lime will usually prove beneficial. The end of the paper be inserted in the soil should not be handled, because often such andling will produce a red coloration of the litmus, and without roper precaution is exercised, this change might be ascribed to the il. See that the end of the paper applied to the soil is distinctly lue when inserted. Blue litmus will invariably be changed to red acid soils, and red litmus to blue by distinctly alkaline soils. intly alkaline soils will be neutral to test paper."

OUR OLD FRIEND THE PLANTAIN.

The first cargo of bananas sent from Costa Rica to the United ates left Limon in February of 1880, and consisted of 360 bunches, ich an enterprising planter picked from the plants growing between the rows of his coffee shrubs. The experiment succeeded so well that he concluded to let the coffee go and stick to banana culture exclusively. Four years later there were 350 banana estates in Costa Rica. Fruit companies had been established, steamers out expressly for the trade, and the annual output was averaging 500,000 bunches. Now there is scarcely a hamlet in the United States where bananas may not be found at all seasons of the year, most of which come from Central America and the West Indies.

Richard Villafranca, formerly the Costa Rican Consul in San Francisco, Cal., published some important bulletins on banana-growing a few years ago. He reckons from the average plantation of forty manzanas (about sixty-nine acres) and takes into consideration all the difficulties to be overcome, such as bad roads, scarcity of labour, high price of seed, etc., and also calculates that the planter has not money enough to buy his land and improve it, too, but has been compelled to borrow money by mortgage on his property at six per cent. a year. Given sixty-nine acres of wild land, the cost of cutting down the under-brush, clearing, burning and planting (with 270 suckers at $25 per hundred) and five weed-clearings would be in the neighbourhood of $3,070. Adding board and expenses of an experienced overseer at $30 per month and six per cent. interest for twelve months on the money invested, brings the cost of the first year up to $3,635. The second year fewer weed-clearings are needed, but 54,000 bunches of bananas are to be cut, a portable house is needed, ploughs and other agricultural implements, all of which together with the overseer's wages and interest at six per cent. may bring the total cost at the end of the second year up to $8,445.

Now for the other and more agreeable side of the question. Forty manzanas of land originally planted with 270 suckers now have at least 10,800 suckers, yielding at the lowest calculation five bunches each, or 54,000 bunches. The lowest price at which they were ever sold is fifty cents the bunch. Deducting all expenses, you have a net profit at the close of the second year of $15,556 or thereabouts. Do you know of any other sure business, short of the Klondyke, which yields equal returns?

In the foregoing statement the cost has been reckoned at the very highest and the sales at the lowest. If the land does not need to be cleared and burned before planting, the cost will be materially lessened, and if the planter does not need to borrow money, he will have no interest to pay. No count has been made, either of the sale of bananas between the tenth and the twenty-fourth months, or of other crops or fruits which he may in the meantime be raising. There is hardly any occupation in which a man is so certain to realize a decent income on a thousand dollars capital—always provided that his plantation is within easy reach of some port to which vessels come from New York, New Orleans or London. That is of prime importance. For the rest, he has merely to tickle the soil and it laughs with a harvest. He need not take any risks at all.

ON FOREIGN FLAVOURS IN TEA.

Their Origin and Prevention.

A troublesome peculiarity of tea is its susceptibility to taints variously described by tasters as "mintiness," "tarriness," "cheesiness," etc., each representing some flavour foreign to the natural flavour of tea. Manufacture, packing and transit have each in turn been charged with introducing the contamination, but it is more likely that particular taints have each their own stage in which the mischief is done. It may be assumed that the origin of any foreign flavour would yield to investigation, but unfortunately this is seldom possible, except in a very cursory fashion.

A very probable explanation of the flavour or taint known as "mintiness" is to be found in the presence of the jungly Ageratum, known as "Elami," in the latter half of the season on gardens well cultivated during the first half, but allowed "to rip" somewhat from August onwards, in order that all hands may be employed at plucking. This weed has a decidedly minty smell and taste. Of tall growing habit, it comes up through the bushes and is gathered only too readily by the nimble hands of the plucker intent on earning extra pice for weight over the appointed task. In many cases it would indeed be hard to avoid picking a tip or two of Elami along with the teak; but as baskets begin to fail in the bottoms, it is frequently gathered in large bunches to stuff a hole, which bunches are, of course, dumped down in the withering house with the tea leaf. A few fragments manufactured along with the tea will inevitably taint a large bulk with the unmistakable flavour of mint. Planters are

alert to prevent the mischief, but Elami leaf very much resembles tea leaf in the withered state, and where it is much in evidence on the garden, it is no wonder that it sometimes gets into the manufactured tea.

It used to be thought that the packing was chargeable, and learned explanations or theories have been put forward attempting to show that between tea perfectly dried and the lead lining of a tea chest a chemical action was induced, resulting in an objectionable "cheesy" taint. This explanation, however, was not convincing. That in some instances it should be the right one, the condition of the lining should have been the proof. Then the different woods used for packing cases came in for condemnation until hardly a single wood indigenous to any tea district in India was without objection. If there was any reality in the theory of scented wood, the faults set down to wooden chests should have disappeared on the introduction of metal, and we have not heard that such is the case. It would probably be more profitable to consider whether tea retaining more than a certain safe percentage of moisture—which Bamber shows to be astonishingly large—is not influenced unfavourably by the stewy heat in the hold of the ocean steamer.

Those interested only in the transport of tea are naturally unwilling to admit that any blame can be laid to their door, but it is becoming very clear to tea men that almost any taint may be contracted by tea on shipboard. Most people are happy when they can get a big shipping company to rail at, and one might unduly exaggerate the case, but the matter is one of easy proof and has, as a matter of fact, been proved over and over again.

So delicate and susceptible is tea that we are not at all certain that the taint known as "tarriness" may not arise from the tarpaulins used to cover the boxes in the first stage of their transport by cart or boat. When we consider that an invoice of tea may often be a couple of weeks on the way before it reaches proper shelter, exposed to rain and sun alternately, which makes the paulins strongly odoriferous of tar and oil outside, it is easy to conceive the condition of the hot oven underneath. It is satisfactory to note that the newer kinds of coverings are designed to avoid this salient fault of the old tarpaulin.

This liability to taint is undoubtedly a strong argument, if such were needed, against much handling of tea between the producer and the consumer. Each separate operation—warehousing, bulking, blending—necessarily increases the risk. We are familiar with reports of rough usage in London warehouses, which is said to more or less spoil some kinds of tea, and it is just possible that a none too nice attention to the delicacy of the article may be chargeable with the introduction of taints into at least samples of the bulk where none before existed. Our own factory system of packing before the advent of packing machinery was none too cleanly, and, we fear, it is yet the case on many gardens.

We are not quite satisfied that the flavour of hand-made China tea, preferred by an ever-decreasing section of tea-drinkers, does not owe something to simple animal taint. It is true that oxidation taking place simultaneously with the rolling process enhances the flavour of the product, but this is a question of degree only, the flavour of hand-rolled China being, it is said, of a different *kind*.

The custom of using resin in soldering the lead lining is probably to blame for the resinous taint, and should be altogether avoided.

Experience would warrant us in assuming that tea is most liable to contract deleterious taints of the "cheesy" class in the finished state, and this consideration led to the green wood and lead corrosion theories. Lead lining is an expensive item, and there seems no reason why paper of a suitable quality should not be substituted.* A great saving in cost and freight would probably be the first result of such a change; a thicker planking could be used, thus increasing the strength and efficiency of the package against rough handling, while we imagine the change would commend itself as a hygienic improvement.—COMMON SENSE in *Indian Gardening*.

[* Vegetable parchment is already in the market, but has never caught on properly.—ED., *Planting Opinion*.]

SEEDS.

THE vitality of seeds has lately engaged the attention of botanical physiologists. Experiments have been made at Kew and elsewhere for the purpose of determining what changes, if any, take place in seeds when placed under conditions of exceptionally low or high temperatures, and the results have been surprising. Seeds which had been subjected to a temperature of 190° C. (340° F. of frost) for nearly five days were uninjured, and germinated freely when sown. Similar results followed the boiling and roasting of certain seeds for half an hour or more. It has been recorded that seeds of poppy, sunflower, and parsley, when made perfectly dry, did not lose their vitality when placed in a temperature of 212° F. for forty-eight hours.

These experiments may lead to results of the greatest practical importance. They show that seeds are capable of supporting, without any loss of vitality, conditions which would be fatal not only to the plants which bore them, but to life in any form. Their condition under these extremes must be one of what is termed suspended animation; and if once this fact can be established, we may expect to find conditions in which seeds might retain their germinative power for any length of time. The germination of "Mummy-wheat" and of the Grecian refuse-seeds, which had lain dormant two or three thousand years, would then seem no longer impossibilities.

Seeds vary enormously in their provisions for retaining vitality, some perishing in a few weeks if kept at rest, whilst others have been known to grow after being kept for a century or more. What the change really is that takes place in a seed, and destroys its vegetative power, does not appear to be known. It is, therefore, to be hoped that the present enquiry will lead to the discovery of some means by which we can keep seeds of all kinds healthy for much longer periods than has hitherto been possible. With our present methods for the treatment and transport of seeds, failure is often experienced. Experiments might be made on such seeds as soon perish under ordinary conditions by keeping them in a frozen condition for a lengthened period, and then sowing them. The experiments already made prove that some seeds, at any rate, were uninjured by extremes of temperature such as they never experience in a state of Nature. As an example of how useful such a discovery would be, we may cite the recent failure of a large importation of seeds of a rubber-tree intended for distribution. It is possible that the refrigerator may be turned to account by the seed-merchant with results as satisfactery as in the case of the meat and fruit merchants.

Much may, however, be done even under present methods by the grower, the harvester or collector, and packer to ensure a longer duration of seed vitality. When seeds are intended to remain dormant for a time, they should be collected only when thoroughly ripe. If known to perish soon, they should be kept in soil or some similar medium. Most kinds of seeds, however, are safest when stored in canvas bags or paper packets, and kept in a dry place of uniform medium temperature. The hermetically-sealed method often proves disastrous.

The longevity of seeds cannot be ascertained by an examination of their shells or structure generally. Seeds may look good, and when sown fail to germinate; whilst, on the other hand, seeds which are shrivelled and apparently incapable of germinating sometimes germinate readily.

The treatment of old seeds whose germinative powers have been weakened from some cause requires careful consideration. As a rule, seeds with hard or tough leathery shells are less liable to perish easily than those with soft or thin papery shells. Every seed has stored up within itself all the materials necessary for the development of the embryo when placed under suitable conditions, but sometimes it is enclosed in a shell so impervious to heat and moisture that it remains unquickened for a long time, and, in some cases, it is unable to germinate.

The seeds of Nelumbium when once dry will lie dormant for several months, even when placed in warm water, but if the shell be cracked, or filed through, germination begins at once. Other hard-shelled seeds behave in the same way, and they have been known to lie unaffected by either heat or moisture for several years until released, as it were, by filing or cracking their shells. SEEDS AND PLANTS
OF
COMMERCIAL PRODUCTS.

Seeds, Cuttings, and Suckers, post free at the following rates :—

Kolanut, new crop now ready, Rs.12—50 per lb. 5 lbs. for Rs.50 (true superior variety).

Nutmeg and Clove, Rs.10 per hundred.

Cacao, best Trinidad varieties, Rs.1,250 per dozen pods, equal to about 300 seeds.

Erythrina Lithosperma, new crop now ripening, Rs.10 per lb.

Vanilla Cuttings, Rs.10 per dozen.

Coca, small leaved kind for low elevations, Rs.4 per 100; Rs.20 per 1,000; large leaved kind for high elevations, Rs.5 per 100; Rs.30 per 1,000.

Giant Kew Pine Apple, Rs.10 per dozen suckers; 5 dozens for Rs.40.

Pepper, best variety, Rs.10 for 1,000; new crop now ripening, 5,000 for Rs.40.

Para Rubber. Orders being booked for the coming crop, available in August-September, quantity limited.

Sisal Hemp, Rs.12 per dozen suckers; 5 dozens for Rs.50.

Liberian Coffee. Orders being booked for January delivery, price according to quantity.

Cinnamon. Orders booked for May-June delivery, price according quantity.

Ramie. Seeds Rs.5 per ounce; root cuttings, Rs.10 per 100, and Rs.(per 1,000.

Fourcroya Gigantia, (Mauritius Hemp,) Rs.10 per 1,000 seedlings; larg quantities on special terms.

Bowsting Hemp. Root cuttings, same price as Ramie; large quantiti on special terms.

Ceara Rubber, fresh seeds all the year round, price according quantity.

Large quantities of all the above supplied on special terms; all orde must accompany remittance by P. O. order.

PLANTS IN WARDIAN CASES.

Para Rubber, Kolanut, Coca, Pepper, Cinnamon, Nutmeg, Cloves, et available for immediate shipment, price on application.

Numerous other seeds, plants, bulbs, suckers, cuttings, etc., supplie large quantities on special terms. *Descriptive Price List* post free application.

oiling water for a few minutes by holding the pot and soil containing the seeds in a bucket, or, if large, removing them from the oil and after soaking in hot water resowing in fresh soil, will often asten germination.

As a general rule, a higher temperature than that under which the arent plant thrives is preferable for all seeds, and the older they re the higher, in reason, should be the temperature. Heat quickens he embryo into activity and softens the wrappers of the seed. Some cultivators are of opinion that the seeds of alpine plants and ndeed of all plants give better results when treated after Nature's lan in regard to heat and moisture. This would hold good were it ot that the seed is often made dry, hard or tough by the treatment necessarily undergoes before it can be sown, and to remedy this an xcess of heat above the normal is necessary. Frost is said to have he same effect on the seed-wrapper as has heat, but speaking from xperience with many kinds of seeds of varying ages, I should say hat old, weak seeds of doubtful vitality are much more likely to germinate under the stimulating influence of a high temperature han otherwise. Seeds of Primula imperials from a very great levation in Java germinated at Kew only when sown in a tropical emperature; and the same is true of Ranunculus Lyalli from the nowclad mountains of New Zealand. The seeds of the hybrid Disas, raised at Kew, were sown in a temperature which would soon kill the full-grown plants. Expert growers of Persian Cyclamen, Chinese Primrose, tuberous Begonia, and many other cool-house plants, sow the seeds in a tropical temperature. Numerous instances of this character might be given. Should any fungoid mould develop about old seeds after sowing, the soil should be saturated with a weak solution of permanganate of potash; or if the seeds are large enough to handle, separate the bad from the good, bathe the latter in the permanganate of potash, and resow in fresh soil.

It is well to err on the side of waiting when dealing with old seeds, as I have known such to remain dormant for two years from no apparent cause, and then to germinate.—W.W. in *Gardeners' Chronicle.*

Pulping, washing, drying, peeling, sorting.

LET us imagine that our coffee is picked and received in the store. It takes ten pikuls of cherry to make one pikul of clean coffee, representing a value of $40, and it takes a long time and has to pass through many manipulations and evolutions before the planter gets in possession of his money, and after all, a good many people may wonder that we get so very little for so much labour and such great risk.

Before we can pulp our coffee we must have a store and pulping-shed. Here, again, is a difficulty. If a planter has the money, or if he can raise the necessary funds, I would advise him to put up at once a decent store on brick pillars and covered with tiles or corrugated iron, large enough to admit his crop being cured there for many years to come. I would advise him to get at once a good oil engine, not less than 16 H.P., to enable him to drive peelers, elevators, pulpers, drying fans, pumps and whatever else he may ultimately require. An engine of 16 H.P. does not cost much more than one of eight, and you get double the amount of work out of it. If you put up a temporary store and temporary pulpers, you will have to keep on altering, adding, improving, changing, until you get sick of it. Finally, you will have to put up a good store after all and get all the machinery. If you have capital, don't waste your time and money in experimenting with temporary sheds and temporary arrangements and inferior machinery. You lose much more that way than you might possibly save in interest on your capital.

But there may be another objection—you may not have the money, and that is a very good reason for not spending it.

In that case, of course, you have to make the best of it; try to sell your cherry to a neighbour; this in such a case would be the most satisfactory thing to do; but should this be impossible, then raise an atap shed for a few dollars and buy one of Walkers' small disc hand-pulpers for £18; you will find that you will be able to do all your pulping until such time as you can afford to buy a larger one and to build a proper store; or, if even this is too expensive, buy an ordinary crusher and a sieve and get through as well as you can. You will always be able to find a market for coffee in parchment, as I shall mention later on. But, whatever you do, don't dry your cherry in the skin. This is called the native style of curing. It is a most difficult task to cure dry cherry, and coffee obtained from dry cherry never fetches the same high price in the market as coffee pulped and cured in the ordinary way, although, as regards flavour and quality, I have no doubt the coffee cured in the native fashion is far superior; but it does not look so nice and even, and also has not the same bright appearance as the former, and appearance must be, or rather is, paid for in coffee as well as in everything else.

I cannot of course give much advice about the store; this depends entirely on the funds and capital at the planter's disposal; but I should say, whatever you do, do it so that you can utilise what you have done in your future improvements. A store generally consists of a platform, three or four receiving cisterns and one washing or tail cistern.

I would not advise less than four receiving cisterns, and, besides the tail cistern, another one to catch the pulp, which always contains a certain amount of coffee, and it will therefore pay the planter to

"PLANTING OPINION" OFFICE,
Nos. 11 and 12, 2nd Line Beach, Madras.

wash the pulp once more carefully before allowing it to be used for manuring purposes.

My reason for advising four receiving cisterns is that Liberian coffee after being pulped should ferment for three days before being washed; it requires therefore four tanks if you want to work continually. The fourth day you pulp into cistern No. 4, whilst you wash the coffee in tank No. 1, the fifth day you pulp into No. 1 and wash the coffee in No. 2, and so on. To show better what I mean, I will give later on a small sketch and plan of an ordinary coffee store and pulping shed.

Below is your pulping-shed and above is the store. A building like this will cost about $1,000 to $2,000; it all depends of course on what kind of material you use and whether you cover the building with atap or corrugated iron, and whether you use jungle wood or merbau square beams, etc. You can spend five or six thousand dollars for the same store and more even; but for one to two thousand dollars, you should be able to get a good building, sufficiently strong to stand all the pressure that is ever likely to be put on it.

The next item is the pulping. There are many different kinds of pulpers, but the best pulper for Liberian coffee which I know, and which I would therefore recommend to every planter, is Walkers' disc pulper. A Walkers' small hand pulper will pulp about ten boxes of cherry in an hour, and eight men in the store are sufficient to do all the work. Sixty boxes is a fair day's task for the men to pulp, as it must be taken into consideration that it is very hard work. If you have a lot of coffee to pulp, keep two gangs of coolies, and relieve them after they have finished 50 or 60 boxes.

To avoid discolouration, be careful not to mix your parchment with any more pulp than you can help, and it must be kept in mind that at no future period will it be so easy to separate the skin from the parchment as when pulping or washing. Parchment when it is freshly pulped is of a clean white colour, and it will keep so as long as it is kept in flowing water; if it is stored in a dry place and mixed with pulp (that is, the flesh or skin of the berry), it will turn brownish red. A good strong supply of water is required to pulp Liberian coffee.

The day's pulping being finished, cover up the parchment and leave it alone for three nights. During this time it will ferment. I don't think that this is done with any idea of improving or affecting the quality, but simply to get rid of the saccharine matter.

When the coffee is pulped, it is divided in skin and parchment; skin is the pulp which has been removed from the berry and parchment is the part of the berry that remains; this parchment is covered with a thick and sweet coat of flesh, which sticks to it and cannot be got rid of until it has been exposed to a process of fermentation.

This takes from two to three days, and the parchment during this period gets so hot that you cannot bear your hand in it for any length of time. When you can easily squeeze the flesh off the parchment, the fermentation is sufficient and the next thing to be done is washing. For this purpose the parchment is uncovered and spread about in a cistern and a number of coolies tread the flesh off. This being thoroughly done, clean water is turned on and renewed as often as necessary, until the saccharine matter is quite washed away. You can hear it distinctly when this is the case, as that parchment when raked up sounds like wood being rubbed against wood, whilst so long as the saccharine matter is still on it it does not make that noise.

CENTRAL HOTEL.

Advertisers are notified to send all advertisement matter and answers to advertisements direct to Manager, this paper, 11 and 12, Second Line Beach, Madras.

Correspondence and matter for publication to be sent to Editor, this paper, Coonoor.

When the parchment is thoroughly washed it is measured aga into boxes of 18″ × 18″, and you will find that 100 boxes of pulp cherry will give an outturn of about 24 boxes of wet parchmer The wet parchment should be taken straight from the washi cistern to the barbecue. If this is done it will keep a white colou otherwise it will get darker. The colour of the parchment does n in any way affect the quality of the coffee, but yet planters like turn out as white and clean a sample of parchment as possible; ve often, however, this whiteness is obtained at the expense of t quality of the coffee, owing to leaving the parchment after it washed in flowing waterf or some days more.

A barbecue is a place used for drying the coffee; it is general made of bricks and covered with cement. The parchment, spre out on this, is exposed to the sun, and every few hours a cooly tur it over, so that the lower beans also get exposed; this is done simp by the cooly walking through the parchment and stirring it with his feet. It takes at least three days to dry parchme thoroughly.

To see if the parchment is sufficiently dry, take off the skin a bite on the bean; if the bean is stone hard so that your teeth w not make any impression, you may consider the parchment sufficiently dry to be peeled. But before peeling it you aga measure, and you will find that you have lost about 20% in measu ment, or, to make myself quite clear, 100 boxes wet parchment w measure when thoroughly dried only about 80 boxes. On lar estates, where there is a lot of coffee, drying or hot houses take t place of barbecues.

Needless to say this is much easier and quicker than drying exposure to the sun. There are, of course, several varieties of dryi houses; but the simplest and most convenient one, to my mi consists of a perforated iron platform on which the parchment spread out to dry, whilst hot air from a furnace underneath forced by a fan right through the parchment. This system dr the parchment in about 20 hours; it has the advantage of maki the planter independent of weather, and it also makes the peeli so much easier afterwards.

For peeling, as well as for drying in a hot-air house, you requ some more effective power than manual labour. If you have buil good store, you can for some time do with a Walkers' hand-pulpe but when it comes to pulping 200 boxes and more of cherry a d your coolies will not be able to do it and you must have an engi The store has been built for extension and for the erection of machine

If you have no engine, you can buy a small hand-peeler (Smou patent, manufactured by Messrs. Gordon and Co., London, is rec nised as having given great satisfaction); but a hand-peeler w never turn out the same amount of work as one driven by machine and it is much too slow, and I would not recommend anybody to in for it; I would sooner ship my parchment to London and have peeled there. The additional freight does not amount to much, a you may depend upon getting your coffee cured in London in a m conscientious and efficient way at a very small and moderate char per cwt.

(*To be continued.*)

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (April 15, 1898) says Sales were resumed yesterday after a week's interval, and the hea supplies brought forward met a steady demand at fully previous values

About 1,100 bags East India were offered and attracted good competiti fine Home Trade marks realising very firm rates, whilst the medi descriptions sold steadily.

Good prices were obtained for the large quantities of Central Americ catalogued, fine colory Costa Rica, in some cases, being readily dispos of at an advance of 1/- to 2/-.

The Terme market has been quiet owing to the Holidays with only small business passing; quotations at the close show a decline of 6d. si our last.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," 11/12, Second Line Beach, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 11 and 12, Second Line Beach, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 20th May, 1898.

Season Reports should be sent to the Printers, Messrs. Addison & Co., direct, and not to *Planting Opinion* Office.

Nilgiris.

Coonoor, 11*th May*.—South-west winds and rain again in full force, though as usual here a great deal more of wind than rain. The coffee blossom promises to be a great success all round, though some prognosticate that the eventual "setting" will be by no means as successful as it seems to be now. Personally I incline to the more hopeful view. Tea is showing scant signs of improvement in yield, and hope is fixed to what autumn may bring forth. Influenza about, and health generally very indifferent.

Kullakamby, 11*th May*.—*Weather*.—Alternate spells and bright sunshine and cloudy weather; one slight shower last week, but more rain wanted. *Crops*.—Good blossom out, and most of it well set. *General Health*.—Fever still very prevalent. *Labor*.—Paid off on lower estates.

IMPORTANT INSECTICIDES.

The use of Insecticides has been much debated by South Indian planters of late years, and although no very great progress has been made a few men, at least, are trying to push the matter forward. Our American cousins have

already gone ahead, and we now proceed to cite some of their conclusions, in the hope that, after making allowances for differences of climate, &c., some of our readers may find them useful. The following extracts are from a bulletin prepared for the U. S. Department of Agriculture, by Mr. C. L. Marlatt, First Assistant Entomologist. As this gentleman remarks, "for the intelligent and practical employment of insecticide it is necessary to comprehend the nature and method of injury commonly due to insects." The great mass of the harm to growing plants from the attacks of insects falls, he observes, under two different heads based on distinct principles of food economy of insects, viz., whether they are biting (mandibulate) or sucking haustellate), each group involving a special system of treatment. For biting or gnawing insects, arsenicals furnish the surest and simplest remedy, unless where the parts treated are to be shortly used for the food of other animals or of man. For sucking insects, it is necessary to use substances which will act externally on the bodies of the insects, either as a caustic or to smother or stifle them by closing their breathing pores, or to fill the air about them with poisonous fumes. Of value also as repellants are various deterrent or obnoxious substances. Besides the above two groups, however, there are (1) the internal feeders, such as wood, bark and stem borers, species living within fruits, &c.; (2) household pests, and (3) animal parasites.

ARSENICALS.

Mr. Marlatt sets arsenicals in the following order in point of solubility and corresponding danger of scalding foliage—the least soluble first:—Arsenite of lead, Paris green, Scheele's green, and London purple. He then proceeds to discuss

HOW TO APPLY ARSENICALS,

and says:—There are three principal methods of applying arsenicals. The wet method, which consists in using these poisons in water in the form of spray, is the standard means, secures uniform results at least expense, and is the only practical method of protecting fruit and shade trees. The dry application of these poisons in the form of a powder, which is dusted over plants, is more popular as a means against the cotton worm in the South, where the rapidity of treatment possible by this method and its cheapness give it a value against this insect in the essentials. This method is also feasible for any low-growing crop, such as the potato, young cabbages, or other plants not to be immediately employed as food. The third method consists in the use of the arsenicals in the form of poisoned baits, and is particularly available for such insects as cut worms, wire worms, and locusts in local invasions.

The Wet Method.—Either Paris green, Scheele's green, or London purple—may be used at the rate of 1 pound to 100 to 250 gallons of water, or 1 ounce to 6 to 15 gallons. The stronger mixtures are for such vigorous foliage as that of the potato for the Colorado potato-beetle, and the greater dilutions for the more tender foliage of the peach or plum. An average of 1 pound to 150 gallons of water is a good strength for general purposes. The poison should be first made into a thin paste in a small quantity of water and powdered or quick lime added in amount equal to the poison used to take up the f arsenic and remove or lessen the danger of scalding. An excess of li will do no injury. The poisons thus mixed should be strained into t spray tank or reservoir, care being taken that all the poison is p verized and washed through the meshes of the strainer. The use the lime is especially desirable in the case of the peach and plum, t foliage of which, particularly the former, is very tender and easi scalded. To the stronger foliage of the apple and most shade tre Paris green may be applied without danger at the strength of 1 pou to 150 gallons of water; with London purple it is always better to u the lime. The arsenite of lead is prepared by carefully pulverizi and combining, in a small quantity of water, the weight of the t ingredients needed at the strength decided upon as indicated by t capacity of the spray tank. The chemical combination is effected i few minutes, and the resulting milky mixture is ready for the ta Lime is not needed with this arsenical. At slightly greater exper this arsenical can be procured already combined as a dry powd white or colored with a dye. If it be desirable to apply a fungicide the same time, as on the apple for the codling moth and the ap scab fungus, the Bordeaux mixture may be used instead of wat adding the arsenical to it at the same rate per gallon as when wa is used. The lime in this fungicide neutralizes any excess of f arsenic and makes it an excellent medium for the arsenical, removi as it does, all liability of scalding the foliage and enabling application of the arsenical, if necessary, eight or ten times strong as it could be employed with water alone. The arsenic cannot be safely used with most other fungicides, such as t sulphate of copper, eau celeste or iron chloride solution, the scaldi effects of these being greatly intensified in the mixture.

The Dry Method.—The following description applies to the pole a bag duster commonly used against the cotton worm: A pole 5 to 8 fe long and about 2 inches in diameter is taken, and a three-fourt inch hole bored through it within 6 inches of each end. Near ea end is securely tacked a bag of "8 ounce Osnaburg cloth," 1 fo wide and 18 inches to 2 feet long, so that the powdered poison m be introduced into the bags with a funnel through the holes at t ends of the pole. The bags are filled with undiluted Paris gree which is generally preferred to London purple on account of quicker action, and the apparatus is carried on horse or mule ba through the cotton fields, dusting two or four rows at once. T shaking induced by the motion of the animal going at a bri walk or at a trot is sufficient to dust the plants thoroughly, or t pole may be jarred by hand. The application is preferably made early morning or late evening, when the dew is on, to cause t poison to adhere better to the foliage. From 1 to 2 pounds are requir to the acre, and from 10 to 20 acres are covered in a day. T occurrence of heavy rains may necessitate a second application, b frequently one will suffice. This simple apparatus, on account of effectiveness and cheapness, is employed throughout the cotton b to the general exclusion of more complicated and expensive mac nery. With the patented air blast machines for the dry distribution poisons, arsenicals are diluted with ten parts of flour, lime, or grou gypsum, and from 60 to 75 acres may be covered in a day by usi relays of men and teams. Greater uniformity is secured with the machines in distribution of the poisons, but their cost (from $30 $60) prevents their general use. The planter should have a goo supply of poison on hand, apparatus for its application prepared advance, since when the worm puts in an appearance its progress very rapid, and a delay of a single day may result in materi damage to the crop. If small garden patches are dusted wi poison by this or similar means from bags or with hand bellow it is advisable always to dilute the poison with ten parts flour, or preferably lime, and for application to vegetabl which will ultimately be used for food, as the cabbage, 1 oun of the poison should be mixed with 6 pounds of flour 10 of lime, and dusted merely enough to show evenly ov the surface.

As poisoned bait.—It is not always advisable or effective to app arsenicals directly to the plants, and this is particularly true in t case of the attacks of the grasshopper and of the various cut worn and wire worms. In such cases the use of poisoned bait has prov very satisfactory. For locusts, take 1 part by weight of whi arsenic, 1 of sugar, and 6 of bran, to which add water to make a w mash, place a tablespoonful of this at the base of each tree or vine, apply a line of baits just ahead of the advancing army of gras hoppers, placing a tablespoonful of the mash every 6 or 8 feet, a following up with another line behind the first. For baiting c

orms and wire worms, distribute poisoned green, succulent vegetaon, such as freshly cut clover, in small bunches about in the infested lds, dip the bait in a very strong arsenical solution, and protect om drying by covering with boards or stones. Renew the bait as ten as it becomes dry, or every three to five days. The bran-arsenic it will also answer for cut worms.

TEA PESTS AND BLIGHTS.

Second Notice.

In a recent issue we had occasion to draw prominent attention to Dr. Watt's valuable and extremely suggestive ork on the pests and blights of the tea-plant. It was rearked that the great principle that underlay most of his ggestions for remedial treatment was to show how to reove the very conditions that favour, may almost invite, sease. It is our present purpose to examine in some tail the various methods proposed, confessing from the st that we are strongly biassed in their favour.

nprovement of seed. In our former article we noticed the deserved prominence given to e improvement of seed, the importance of which in relaon to coffee has many times been forcibly set forth in these ges. Were it not for that curse of Anglo-India, the ant of continuity in experimental work, it is highly proble that pedigree tea and coffee seed capable of producing ants of phenomenal yield and extreme hardiness, would among the commonplaces of the Indian planting industry. ut as no one experimenter can hope to reap the full or en a just share of reward of his labours in this direction, e subject has been most unwisely relegated outside the here of practical planting.

ltivation. In examining the current methods of cultivating the soil in Assam, r. Watt is by no means convinced of the alleged ultraerfection arrived at by constant hoeing or digging the soil, as to keep the surface of the land absolutely free of eeds. Besides the weed question, the tillage of heavy soils n be very easily carried to excess, inasmuch as the soil rticles already very fine in clay are rendered smaller d smaller by constant stirring. This results in the soil beming more compact and more impervious to the free passge of air and moisture. Further the practice also tends oxidise too quickly what organic matter there is in the il. In writing, however, of the advantages rendered by a oderate growth of weeds to the soil, Dr. Watt falls into ror when he supposes weeds tend to keep the soil moist the hot weather. The exact contrary is the case. Much ould be done, recommends the learned author, to enurage leguminous weeds in the tea, as their manurial alue would be of course immense. The marked beneficial fect on tea produced by the *Sa*, a leguminous tree, is well cognized throughout Assam, and the only objection to its eneral adoption lies in its shade, which of course seriously ffects the quality at least of the flush that grows under it.

rainage. From cultivation to drainage is a natural step in reality, though the timate connection between the two branches of work is rely recognised. We might, indeed, go further and say at really efficient drainage, *is* cultivation. For the generally accepted idea of drainage, *i.e.*, to relieve soil of its superfluous moisture is by no means correct. The real objects that should be aimed at are to increase the depth to which water will penetrate, thus deepening the arable soil and improving its condition, the removal of excess of moisture being one of the incidential results. For water, especially rain water, is one of the most potent of the solvent agents of nature. It attacks and renders soluble the various minerals in the soil. And if given a free passage to some underground exit, it leaves channels by which air freely enters and completes the solvent and sweetening work begun by running water. Heavy soils, especially if flat, almost always need artificial subsoil drainage, but light sandy soils are porous enough in themselves, and drainage in their case may well be neglected. Save in so far that the stoppage of surface wash is of course an essential, whatever the nature of the soil. Many planters imagine that perfect drainage may in dry weather tend to dry up the soil unduly. Subsoil drainage, however, can only remove excessive moisture, and in doing so increases the depth of soil which can absorb moisture, so that it actually allows the the soil to retain, in times of drought, more moisture than were otherwise possible. This seeming paradox is easily understood, when it is remembered that if a soil is pervious to water to a small depth only, the excess must run off the surface. Subsoil drainage, by allowing the water to penetrate to a much greater depth, enables it to absorb almost all the water that falls on it, passing out the excess below the surface, thus stopping surface flow and wash automatically.

The main object of all drainage is, as may be guessed from the above, to induce every drop of water that falls on the soil, to penetrate into it to the greatest possible depth. Tested by this principle, it is evident that the drainage systems current on almost every Indian and Ceylon plantations are absolutely wrong. The usual drain is a shallow catch drain to arrest the flow of surface water. Good subsoil drainage would have prevented any such surface flow from taking place at all, excess of moisture should only escape from the soil after having percolated through it. Open drains are perhaps the only ones practicable on most estates, as the cost of tile drainage is excessive, running into many hundreds of rupees per acre. Dr. Watt, while admitting the tremendous cost of closed drains advocated, frankly says that he has not attempted to do more than suggest improvements on the present methods. He states that the economic side of the question has been left for practical men to deal with. Not an excellent point of view this, as impracticable remedies are surely of no importance to business men who have to deal with stern facts. It would have been far more to the purpose had Dr. Watt devoted more attention to the only practicable, *i.e.*, open plantation, drainage, with a view to its improvement. His suggestion in this direction only amount to the following: drains should be deep and narrow, and that their sides should be banked up to stop surface flow and encourage percolation. We would ourselves suggest as a great improvement on the present methods of catch drains, trenches and water-holes, a carefully worked out combination of all three. Main drains, deep and as narrow as practicable, should follow the course of every nullah or water-course, and additional ones dug when the natural escapes are insufficient. Tea, coffee or shade

trees should be planted close enough to protect these drains from being unduly exposed to the air. The rows of trees should be so planted that drains can be dug between the rows at a good gradient towards the main channels, without necessitating the removal of any trees, catch or surface drains should only be used to prevent the flow from uncultivated land flowing on to the cultivation. To replace the cross or catch drains in the cultivation itself, we would advocate a complete chain system of water-holes, so dug as to allow free percolation from one to another until the excess finally escaped in the doom or main drain. We are, of course, writing with especial reference to the steep lands of South Indian plantations. On flat land such a system would be impossible.

On stoney land, a species of subsoil drains would be easily worked at a very small outlay. Deep narrow drains should be dug at frequent intervals, the nearer the better. They should be filled in with rough stone, the larger pieces of course at the bottom, till within say a foot of the surface, when they might be covered over with earth. Where stones are insufficient, loppings of shade trees, *if free from blight*, might be used instead, and gradually filled in as the seasons pass. Burying vegetable matter, especially prunings from coffee or tea is, however, subject to grave objection, as many plant diseases rest in a quiescant state in dead wood, subsequently emerging into active life and attacking the living trees around. But where prunings and loppings are left to decay on the surface, they might well be used as suggested. They should, however, preferably be removed and burned in their green state.

To conclude, we may mention that the distance apart of lateral or feeding drains is determined by the slope of the land, the character of the soil, and the depth of the drains. Mr. Dempurgh's tables gives the depth of drains in clay soils at $2\frac{1}{2}$ to $2\frac{3}{4}$ feet, 15 to 21 feet apart. For medium soils 3 to $3\frac{1}{4}$ feet deep, and 21 to 30 feet apart. For porous soils $3\frac{1}{2}$ to $4\frac{1}{2}$ feet deep and 33 to 60 feet apart. These tables are, we fancy, for fairly level land. We presume that more frequent drains would be required were the land steep.

NOTES.

Jolted out of the ruts! It was not to be expected that the tea planters of Upper India would let pass without remark Dr. Watt's strong criticisms on the modes of latter-day tea cultivation. There is no doubt that Dr. Watt, as we have ourselves pointed out, has made certain blunders and fallen into errors not a few. Annoyed with his assumption of superior knowledge, and the somewhat radical changes he advocates in cultivation and pruning, a writer in *Capital* attempts, though unsuccessfully, to sneer down "Tea Pests and Blights" *in toto*.

South Indian Teas. Messrs. Arbuthnot & Co's monthly report, dated London, 15th April, says :—

"Supplies, were heavier than of late and the public sales included 5,849 packages sold at $6\frac{1}{8}$ per lb. average, compared with 1,500 packages at $6\frac{1}{2}$ per lb. in February. The majority were of ordinary character, and having to compete with an abundance of similar description from both North India and Ceylon prices in most cases ruled easily. Fairly useful Invoices were, however, sold from several estates, and it is to be hoped that climatic influences may soon be again favourable to the general manufacture of teas with good col liquor, such as used to be sent from Travancore and for flavo Invoices from the Nilgiris and South Wynaad."

"The Coffee Planter's Manual." We have received for review copy of the fourth edition of wh has been long favourably known Brown's Coffee Manual, edited and brought up to d by Mr. J. Ferguson, the Editor of the *Ceylon Obser* and *Tropical Agriculturist*. The whole of the last editi (1894) has been re-arranged, and a good deal of n matter has been added, referring more especially to Liber coffee. Mr. Ferguson has also included useful pap containing summaries of discussions on manuring, chemi analyses of soils, agricultural experiments bearing on cof culture, the enemies of coffee, estimates of crops, and oth practical subjects of interest to the coffee planter of t present day. But why does Mr. Ferguson apply so un-ag cultural a term to forking as "puncturing the earth"?!

The future trade in Indian plantains. We have given a good deal attention to the share Indian plant might secure of the dried bana trade, but have rather discouraged the idea of creating green fruit export. *Indian Gardening*, however, in comm with the *Madras Times*, sees great possibilities in the gre fruit trade, and alleges that there are Indian varieties of t banana, or plantain, that are unequalled for flavour a appearance in all the world. The great difficulty of cou lies in the cold storage that would be essential, and t present inadequate accommodation in this respect in t Indian liners.

Considering the very great advantage that would res to India as a whole, from the development of an exp trade in fruit, it is not unnatural to suggest that Gover ment might well depute some of its hybrid Land Records a Agriculture officials to conduct exhaustive experiments initiating the trade.

London Market. The *P. M. Review*, of 16th ultim says :—*Coffee.*—During the holida there have been some very heavy arrivals of Costa Rica a other Central American descriptions, and in consequen the catalogues on Thursday and Friday, when the auctio were resumed, contained a larger quantity than at a previous time this year. The demand showed a decid improvement, particularly for home trade kinds, and pric have steadily advanced. Medium and fine Costa Ri are from 2*s*. to 3*s*. dearer, and the lower grades have al sold at rather higher rates. Of the small quantity of Ea India offered Mysore fetched full prices, the bold being some cases dearer. Guatemala has been quiet, but valu show little change. In the terminal market quotations ha slightly eased off, varying from 6*d*. to 9*d*. below those of week ago, although some of the foreign markets, notab that in New York, are decidedly dearer.

FOR SALE.—Hand Camera ($\frac{1}{4}$ plate) by Robinson, Dubli in first-class condition with 12 slides for plates—also son $2\frac{1}{2}$ dozen plates (more or less), 6 developing dishes, 3 optim printing frames, and large assortment of photographic chemica Price on estate Rs.75. No offers. Apply—M. W. LITTO Shaniwarsanté, N. Coorg.

Indian Teas.—The market has been practically closed nce our last issue as no public sales have been held, while ransactions by private contract have been on a moderate cale. The demand, however, is steady, and a fairly good usiness has passed in most grades, and it is probable that here will now be a better inquiry. The deliveries are im-roving, while the trade have bought sparingly for some ime past, thus reducing their stocks in bond, which it will e necessary to replenish before long. For the opening ales on Monday there are 22,537 packages catalogued, ost of the teas being of inferior quality, the proportion of he finest kind being exceptionally small. For the latter, rm prices are likely to prevail, while the former will robably not be affected, as the supply for some time to ome will no doubt be ample to meet any increase in the emand. Medium descriptions are fairly represented, and hose giving a good infusion are sure to be well competed for t prices quite equal to those prior to Easter. Telegrams rom Calcutta give the total yield available for this market s 234,000,000 lbs., as compared with 131,770,000 lbs. last eason, while nothing definite is known as to the probable esults of the coming crop.

LETTERS TO THE EDITOR.

WIRE SHOOTS.

SIR,—I want to know how to work a single wire rope, aided by a paralled cotton rope, so as to bring *up* firewood, tea-leaf, etc., from the bottom of my estate to the factory. The down oad would of course be manure, etc., eked out by stones and so on. Rise about 300 feet, span about $\frac{1}{2}$ mile. Could a man haul up, say a 50-lb. load without a winck, and without a down oad to help him. What would be the weight of the down load to bring up a 50-lb. up load? All information on the subject would be very grateful to

SINGLE WIRE.

HOPPERS IN TEA DRIERS.

SIR,—There are still, even in this year of grace, unfortunate mortals who have to worry along minus siroccos and such blissful appliances for drying tea. I am one of these unfortunate mortals. And I want to know two things. One is the best form and cheapest of a furnace to get up sufficient heat for ten (down draft sirocco size) trays. Second, the best kind of valve and hopper to use to regulate the heat and yet not to deaden it altogether.

RIP VAN WINKLE.

THE "LADYBIRD HEAD QUARTERS."

SIR,—Will you kindly insert the enclosed correspondence in the next issue of your paper, as I think an explanation from me is necessary, in reference to what Mr. H. O. Newport states, in his second narrative report published in *Planting Opinion*, of 29th April, 1898, regarding his head quarters on his return to India.

PERYOOR ESTATE, DINDIGUL, *7th May*, 1898. } FRED. R. GERRARD.

L. P. P. ASSOCIATION,
DINDIGUL, *7th May*, 1898.

To

H. ORMEROD, ESQ.,
Secretary, U. P. A. S. I.,
Madras.

SIR,

I thank you for your Circular letter, dated 27th April, 1898, forwarding copy of Mr. H. O. Newport's second narrative report, dated Brisbane, 2nd April, 1898.

Mr. Newport seems to take exception to my writing to the Managing Director, N. P. Co., for permission to use the Pillavally bungalow as his head quarters on his return to India.

I enclose copy of my letter to Mr. Ramsay.

The fact of Mr. Newport wishing to know from me where his head quarters are to be on his return to India (*vide* his letter, dated 27th Jan., 1898), rendered it necessary for me to take things into my own hands and arrange matters, and I think you will agree with me that I could not at a general meeting of my Association inform the members that Mr. Newport could have the use of the Pillavally bungalow to carry out his experiments, without first obtaining the permission of Mr. Ramsay, the Managing Director of the N. P. Co. to do so. It would have been most discourteous for me to have acted otherwise, and I maintain I was right in what I did.

A copy of this letter has been sent to the *Planting Opinion* for publication.

I am, Sir,
Yours faithfully,
(Signed) FRED. R. GERRARD,
Hon. Secy., L. P. P. Association, Dindigul.

PERYOOR ESTATE,
DINDIGUL, *3rd February*, 1898.

MY DEAR RAMSAY,

Before leaving, Newport wrote to me to say that Mr. Romilly had suggested that all correspondence during the time he was in Australia should be addressed direct to me as Hon. Secretary, L.P.P.A., and to Mr. E. G. Windle, Hon. Secretary, N. P. A. Among other things Mr. Newport wishes me to decide, is his head quarters on his return to India.

In his letter to me he says :—"I shall want to know as soon as possible what are to be my head quarters, on my return, and where I am to take my consignments to on my return to India. This point must be settled, as it will not be possible to delay once the consignments are out, and it may also be necessary to make some sort of preparation or arrangement to receive them."

In writing to Mr. Windle I suggested, that as the green bug is still bad here, Mr. Newport's head quarters should be located on the Lower Pulneys, and that one of our bungalows would be placed at his disposal.

There will be a meeting of the L. P. P. A. on the 12th instant, when I should like to see this matter decided.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,
Shencottah.

Mr. Newport will probably return to India in four months. I write to ask if you will kindly allow him the use of the Pillavally bungalow on his return to carry on his experiments with ladybirds till the expiration of his leave with you. I shall be glad if you will kindly give me a reply to this before the 12th.

Yours sincerely,
(Signed) FRED. R. GERRARD.

GENERAL ARTICLES.

THE U.P.A.S.I. SECTION.

[UNDER THE CONTROL OF THE SECRETARY, U.P.A.S.I.]

THE following is a list of the names of planters in England or about to proceed there that have been submitted to Mr. Acworth in connection with the Currency question :—

The Hon. Mr. H. P. Hodgson	...	(Nilgiris.)
H. W. Leeming	...	(Shevaroys.)
Henry Gompertz	...	(Do.)
H. M. Hall	...	(Nelliampathies.)
R. H. Elliott	...	(Mysore.)
Brooke Mockett	...	(Do.)
Alfred Clifford	...	(N. Mysore.)
Baron J. vonRosenberg	...	(Kanan Devan.)
F. Mangles H. Mangles	...	Europe.

* * * * *

Besides this a Captain of the Indian Staff Corps, who has made the Currency question his special study, wishes to give evidence in support of the opinions expressed in the U.P.A. circular issued last December. He has been requested to communicate with Mr. Acworth, to whom his name has been forwarded.

* * * * *

The Hon. Mr. Hodgson will leave about the 14th instant, and should arrive home in ample time to give evidence before the Currency Committee.

GREEN MANURING.

(*Continued from page* 197).

SOME of the most interesting observations made by Dr. Schultz refer to the *mechanical improvement* of the *soil* by means of the *penetration* of the *roots* of the *leguminous crops*. This adds greatly to their value as accumulators of nitrogen, by adding humus to the subsoil, and by opening up the latter for the passage of the roots of the alternating crops.

This subject has been patiently studied at Lupitz, the experiments and observations that have been made having regard both to the depth to which the roots of the various leguminosæ themselves extend, and also to the depth reached by the roots of the succeeding plants, compared with that reached by them in similar soil properly manured, but not having borne leguminous plants as a previous crop.

Accompanying these observations, others have been made on the comparative fertility of soil manured with green manure, compared with that of like soil receiving, in the form of farmyard manure, a quantity of nitrogen equal to that supplied in the green manure, the mineral manuring of the two plots being alike. The crops experimented with in this direction have been, among others, rye and potatoes, the exposed roots in the root, measuring experiments having been *photographed* as *well* as *measured*. It was found that when rye followed a lupine crop, the roots of the rye exten ed to a depth of 39 *inches*, while those of the potato grow after lupines, burrowed *deeper still ;* whilst in compani plots manured with farmyard manure, but not having grow lupines, the roots of rye or potatoes only extended to depth of from 15 to 23 inches. The effect of the green manu is well shown in the following experiment on potatoes. field of over 35 acres was in 1893 devoted to a comparati experiment on farmyard manure and green manure (lupin sown after harvesting rye). Two-thirds of the field we green manured by ploughing in lupines thus grown, wh the remainder, on which wheat had been grown (not follow by green manure), was treated with about 8 tons per ac of farmyard manure. The season was an exceptiona dry one, and it was noticed that while on the farmya manure plot, the potatoes were backward and the folia poorly coloured, those on the larger part of the field, whi had been green manured, were vigorous throughout, no withstanding the drought, and bore healthy green foliag It should be mentioned that throughout the field, bo manure (about 3 cwt. per acre) and dried blood (abo 1½ cwt. per acre) were sown. The ploughing prelimina to the sowing of the potatoes was carried out by steam a depth of 15 inches, all cultural conditions, with th exception of the substitution of dung for green manu being as nearly as possible alike in both parts of the fiel The quantity of farmyard manure applied was calculated the basis of the nitrogen estimated to be contained in t green manure. The portion of the field following t lupines ploughed in as green manure gave a crop of 9 to of potatoes per acre. The portion receiving farmya manure in place of green manure gave barely 6 tons potatoes per acre. A deep section was cut in each part the field, in order to study the root development, and was found that while in the *crop following the lupines, t roots penetrated to a depth of nearly* 47 *inches,* those in th portion of the field manured with farmyard manure on reached to a depth of from 15 to 17 inches, the roots in th former case having evidently made their way in the channe formed for them by the roots of the preceding green cro The following table summarises the results :—

	Potatoes grown after lupines ploughed in.	Potatoes grown wi farmyard manur
Depth of penetration of roots...	47 inches.	15·17 inches.
Yield of potatoes per acre ...	9 tons.	6 tons.

Dr. Schultz calculates that the expense of the green cr was somewhat less than £1 per English acre, while the valu and cost of carting and spreading the farmyard manu amounted to nearly four times that sum, the total cost of th potatoes being more than doubled by the use of farmya manure, as compared with their cost when lupines we used as green manure. Mons. Grandeau is this ye himself repeating this potato experiment in the statio Agronomique de l'Est.

A crop of rye, taken after lupines ploughed in, was al subjected to careful stem and root measurement. The pla above ground at the time of harvest measured from 47 66 inches and the roots extended to a depth of nearly 4 inches. In the case of rye grown *without* green manure, th

ollowing potatoes liberally manured with kainit, superphosphate and nitrate of soda, the plant above ground measured 27 to 37 inches, while the roots extended to a depth of only 20 to 24 inches. Another crop of rye was sown on land formerly pastured, which had only been under cultivation a few years and which had only once borne lupines. On this plot the rye above ground measured from 20 to 35 inches and the roots did not extend below about 16 inches. The yield of grain on the three plots respectively, in bushels of 60 lbs. per English acre, was 27 bushels, 12 bushels and 9¾ bushels. The differences are shown in the following table :—

—	Rye		On poor, recently arable land, not having lately borne lupines.
	After lupines ploughed in.	After potatoes heavily manured with artificials.	
Height of plant above ground ...	47·66 inches.	27·37 inches.	20·35 inches.
Depth of roots ...	45 „	20·24 „	16 „
Yield of grain per English acre ...	27 bushels.	12 bushels.	9¾ bushels.

The relation between the root depth, total plant development, and yield of grain thus viewed is very striking.

This notice of Mons. Grandeau's article may be supplemented by the observation that lupines are a crop very little known to English agriculture, although a very familiar one to those in the habit of travelling on the continent. Comparatively few references are made to them in English agricultural text-books, though a note on them, written by the late Professor Lindley, occurs in Morton's "Encylopædia of Agriculture," published as long ago as 1855. Reference is there made to the great depth of their tap roots, and to the power which the plants thereby possess of bringing up alkaline matters from the subsoil, which, on decay, leave the soil charged with mineral matter. They are referred to as being specially valuable on account of the ease with which they can be grown on bad land, such as sandy gravels and thin clays, and the writer adds that "white lupines are already beginning to be quoted in the seedmen's lists."

Mr. Crisp, of Butley Abbey, Wickham Market, Suffolk, experimented with lupines in 1858, and chronicled his experience in the Journal of the Royal Agricultural Society for 1859 (Vol. XX., 1st Series). He grew the crop for grain, and expresses astonishment at the very heavy yield obtained on land of excessive poverty or sterility.

In the same volume of the Journal, Baron H. von Mathusius, of Prussia (who supplied the seed to Mr. Crisp), describes the plant and its cultivation, speaking both of the blue and yellow lupine as cultivated for the purpose of being ploughed in as green manure, as well as being consumed in the green state by sheep and as a grain-yielding plant. He too speaks of the luxuriance with which lupines grow on light, poor, sandy soils, in situations where no other leguminous plant could live. Also in the Journal of the Royal Agricultural Society for 1860 (Vol. XXI., 1st Series) will be found an interesting article by the late Dr. Voelcker, on the cultivation and composition of lupines, in which he records not only his own experience but that of Mr. Kimber, of Lubney, Warren, Abingdon Berks, and of Mr. P. H. Frere, of Cambridge. Mr. Kimber grew from 16 to 21 tons of green crop per acre. The attempt of Mr. Frere, however, to grow either yellow or blue lupines was to use his own words, "a total and costly failure," although season and soil were favourable, and neither Mr. Frere nor Dr. Voelcker could explain the refusal of the land in question to yield a crop. In the light of recent investigation it appears not altogether improbable that Mr. Frere's failure may have been *due* to an *absence* from the *soil* of the *proper* BACTERIA for the *infection* of the *plant* and the consequent production of the ROOT NODULES upon which its success, *like* that of other leguminosæ depends. It is, indeed, not remarkable that difficulties should be encountered in growing for the first time a new leguminous crop upon soil which had hitherto not known it.

Where a soil is mechanically suitable for the growth of a *deep* and *freely rooting plant*, a refusal on the part of the soil to yield a crop of lupines would POSSIBLY be satisfactorily met by *treatment* with Professor Nobe's "NITROGIN," a commercial preparation of the *special bacteria* required respectively by the various leguminous crop already fully described by Dr. I. A. Voelcker in this volume of the Journal (Part II., p. 253).

Lupines are referred to again in the Journal of the Society for 1882 (Vol. XVIII., 2nd Series), by Mr. Joseph Darby, who points out the slight extent to which English farmers are acquainted with them. Despite their extensive growth on the Continent, they still remain practically unknown to the majority of English farmers in any of the three cultivated varieties, except as an ornament in the flower garden. Lupines, as a catch crop, may be taken after an early harvest by being sown as soon as the land can be ploughed for them; or they may be grown as an early spring crop before turnips. They will *not*, however, *stand any serious frost*, and therefore, in our climate, would rarely live through the winter. If fodder should be scarce, they need not necessarily be ploughed in as manure but can be used as fodder. Unless, however, fodder is scarce, they, like other catch crops, are perhaps in the end more economically used by ploughing directly into the soil as green manure than by direct consumption.—BERNARD DYER, *in the Journal of the Royal Agricultural Society of England, December 31st*, 1896.

RAMIE AGAIN.

ITS CULTIVATION, DECORTICATION, TREATMENT AND USES.

THE following notes are issued by Messrs. Macdonald, Boyle & Co., of 39, Victoria Street, London, and may interest some of our readers :—

This well-known and valuable fibre is the product of a plant of the nettle family known as *Bœhmeria nivea*. It grows luxuriantly throughout nearly the whole of the tropics, and especially within 10 degrees north or south of the Equator, where there is a moist climate, and very little variation in the temperature, or in the rainfall throughout the year—the Straits Settlements and the surrounding countries for example. In such a climate the stems can be cut, day by day, as they gradually mature, and the factory thus kept fully employed throughout the year necessitating a small treating plant only. The crop system hitherto adopted requires an enormous amount of machinery to deal with the product of, say, 1,200 acres, within a limited time, irrespective of the difficulty of getting labour.

In an estate of, say, 1,200 acres, we advocate the laying out of three acre blocks—two acres of which are under cultivation and the

remaining acre is devoted to paths—one cooly can attend to each block, as when once started he has only to cut a daily supply of stems; no cultivation being necessary beyond returning to the land the refuse consisting of the leaves (which are stripped off on the spot as each stem is cut) and the ashes from the burnt refuse from the decorticators; the daily cuttings, assuming a crop of 70 tons of stems, per annum, per acre, would be about nine hundred-weight for each two acres.

Assuming the stems to mature in three months, the block would be planted in twelve sections occupying twelve weeks, and by the time the last section is planted, the first should be ready for cutting.

Each section will require weeding until the stems have arrived at about 2 feet high: after that no weeding will be necessary, as no weeds can grow in the neighbourhood of Ramie after the plant has arrived at that height.

If regularly cut, the plants will continue to grow for an indefinite period, but in consequence of the spread of the roots they will require periodical thinning out—removing every other one for instance—care being taken to have other land ready to transplant the roots so as to prevent waste.

Irrespective of other considerations, the system of daily cuttings is important, inasmuch as only ripe stems are cut, and a uniform quality of fibre assumed, whereas by the crop system, ripe, over-ripe, and immature stalks are cut indiscriminately, thus preventing any possibility of uniformity in the fibre.

In order to select suitable land for the cultivation of Ramie, it is necessary to understand the chemical constituents of the plant, these having been found by careful analysis of the incinerated green plants to be as follows: —

Potash	11·8
Soda	2·35
Lime	30·87
Magnesia	7·89
Ferric Oxide and Alumina	2·41
Oxide of Magnesia	0·17
Phosphoric Acid	7·29
Silica	33·01
Chlorine	2·42
	100·5
Less excess of Oxygen due to Chlorine ...	0·5
	100·0

From the above analysis it would appear that the Ramie plant exhausts the soil, but inasmuch as the whole of the refuse from the decorticators (consisting of bark and wood, and the whole of the leaves) is returned to the soil, there remains simply the fibre, which is only $2\frac{1}{2}$ per cent. of the weight of the stems without leaves; under these conditions the exhaustion is more apparent than real.

From experiments undertaken by the United States Agricultural Bureau, the mineral ingredients extracted from the soil were found to be distributed over the whole plant as follows:—Of Potash about three-fifths in the stalk, more than one-fourth in the leaves, while the *bark and fibre contain a little above one-tenth.* Of the Lime 87 per cent. was in the leaves, 10 per cent. in the stalk, and 3 per cent. in the bark. 55 per cent. of the Nitrogen was found in the leaves, 29 per cent. in the stalks, and 15 per cent. only in the bark. So that all that is actually taken from the soil is an infinitesimal amount of the Potash which is contained in the fibre.

In the choice of the land, therefore, it is necessary to ascertain the quantity of the above ingredients it contains. A soil not too heavy should be selected, and be well but not too deeply drained, as the plant is a surface feeder; it grows better in the shade. In clearing jungle, therefore, many of the large trees may be left standing.

METHOD OF CULTIVATION.

When sufficiently cleared, the land should be laid out in blocks of three acres, to which one cooly can attend, as all he has to do after the plants are two feet high is to cut the stems as they ripen and deliver them to the tram line. For the convenience of transport the tram should run through the centre of each block, so that the farthest point to which he will have to carry the stems should not be more than 250 yards, that is, he will have one and-a-half acres on each side of the line, the length of each block being roughly 250 yards; the three acres should be laid out in beds, 6 feet wide, with a pathway between of 3 feet. This will give two acres actu under cultivation. The beds should be turned over about 9 in deep, and the earth from the paths (which should be about 18 in below the level of the beds to carry off the heavy rains into drain) thrown on to them and smoothed over. They are ready for planting.

PLANTING.

If sufficient plants already exist in the neighbourhood, an es may be started with cuttings, rooted layerings, or by means of divided roots. If no plants exist, recourse will have to be to seed.

CULTIVATION FROM SEED.

Sowing.—A piece of any light soil is well dug once or twice, divided into small beds, say six feet by four feet; the surfa pressed down with the back of a spade and made moderately and then raked smooth. The evening before the seed is to be s the beds are watered, the following morning they are lightly r and levelled. The seed, which is very small, is mixed intimately dry earth, which is sufficient for six beds of the size named. mixture is sown evenly over the beds (*not covered with earth*) and lightly pressed down with the back of a spade. Light thin mat stretched on sticks about two feet above each bed to keep them su ently moist, and to protect the germinating seeds from the sun. water is given till the young plants are up, but, if necessary, the s ing mats are sprinkled by means of a broom dipped in water. mats are removed at night, so that the young plants may catch the and they are laid aside altogether when the plants are two in high. If the beds are dry they are now watered, and this is repe whenever necessary. The beds should be kept clear of weeds. soon as the plants are big enough to handle, and before they bec crowded, they are transplanted to the field—a wet day being ch for the purpose; they are taken up with a spade, keeping a s ball of earth round the root of each and planted about nine in apart. The beds should be kept weeded until the plants are 2 high, when no further attention is necessary.

PLANTING ROOTS.

When the plantation is started by roots, they should be pla 18 inches apart.

LAYERING.

The plants can be propagated by means of layering either the seedling or the root; when the plants are grown for the sp purpose of propagation, they should be arranged three or four apart, set slantingly, two or three inches of earth covering the The ground must be kept clean and loose. When the first st have attained the height of about three feet, they are ready layering. The ground then should be thoroughly moistened, the stalks bent gently down, fastened with small crotchets covered with three or four inches of earth, leaving the top of layered stalk uncovered. Care should be taken to avoid detac the stalks from the parent root. In the course of three or weeks the layers will have made stalks which can again be lay for the same purpose, and quite a number of the stalks can be out for transplanting in order to increase the plantation.

Cuttings.

These are prepared by dividing the stalks into lengths of five or six inches. They are set out obliquely, about twelve inches apart, and nearly covered with earth, and if the work is done before the hot weather begins, they will require neither watering nor shading, but must be kept clean of weeds. In two weeks they will have rooted.

Transplanting.

In time the entire space between the rows will have become filled with roots, unless precaution is taken to remove every alternate plant as soon as the rows become overcrowded; but care should be taken to have other land ready for removing the transplanted roots.

Even Growth.

The matter of securing an even growth of stalk is a very important consideration. By even growth is meant not only even length and size of stalk, but uniformity of growth. A stem of Ramie grows rapidly when there is sufficient moisture, but is of stunted and slow growth when opposite conditions prevail. When one of these conditions follows the other in the same growing crop, the fibre is adversely affected, in the after-process, to fit it for spining the chemical treatment, necessary to reduce the hard and stunted growth, to the condition of spinable fibre, may wholly disintegrate the structure of the fibre, in the softer or free grown portion of the stalk, and great waste and loss ensue. Therefore, where lengthened droughts are likely to occur, means of irrigation must be provided.

Crop.

One acre of land should produce at least 70 tons of stems (stripped from leaves) per acre. This means that each cooly will have to cut and bundle, on his 2 acres under cultivation, about 9 cwt. of stems (weighing, say, 6 ounces each) per day, and reckoning 313 working days to the year.

Decorticating.

After cutting, the next operation is to decorticate the stems and separate the fibre. One battery of decorticators will treat the produce of 200 acres. This battery is placed in the centre of each 230-acre block so as to minimise the transport of the stems.

Degumming.

The fibre produced by the decorticators is embedded in a mass of gum and resinous matter, insoluble in water, which must be removed before the white filasse suitable for textile purposes can be obtained. It has therefore to be sent to the degumming shed, where by means of chemical process the cleaning is effected, and a beautiful white fibre obtained; it is then dried and packed for export.

Uses of Ramie.

It would be impossible to enumerate the innumerable uses that Ramie can be put to in the textile industries of the world.

It can be manufactured into goods so widely diverse as lace and heavy sail cloth. When used for the former purpose, one of the peculiar properties of the fibre appears as in finishing the lace Ramie takes a fine gloss excelling that of silk itself, and the same property is manifested when it is made into damasks and similar goods. It will mix well with wool or silk, and can be used easily in combination with cotton.

The strength of the material is shown by the fact that a test of a strip 1½ inches wide and 9 inches long of navy sail cloth made from it showed a breaking strain of 870 lb., which is double that of the ordinary Government test. One factor is important, viz., that canvas made from it does not mildew, so that sails may be furled wet, or canvas hose rolled when saturated, which cannot be done with ordinary canvas made from flax.

Estimate of Plant and Machinery to treat the produce of 400 acres under cultivation.

	£
Two Batteries of Decorticators, including Engines and Boilers.	1,200
One Degumming Plant, including Fittings	500
Engine and Boilers	400
Soaking, Chemical and Water Tanks	250
Steam Barrel, Steam Valves and Fittings	75
Steam Pump and Appliances	100
Belting	50
Weighing and Baling Machinery	300
Freight and Sundries	175
	3,050

This plant will produce about two tons of filasse per day. Estimate does not include the cost of erection, which will naturally vary according to the situation of the estate and the labour available.

Estimate of cost of necessary Machinery for treating the product of 1,000 acres.

Plant and Machinery.

		£
Decorticators 5 Installations of 40 Drums, with 5 12-H. P. Engines		3,000
One Degumming Plant		1,000
Steam Boilers and Engine		1,000
Soaking Tanks		250
Chemical Tanks		250
Water Tanks		100
Steam Pump and Appliances		100
Loading Crane, Weighing Machinery, etc.		500
Fittings for Treating Sheds		250
Steam Barrel, Steam Valves and Fittings		150
Belting	say	100
Baling Machinery		500
Freight and Sundries	say	350
		7,550

The above machinery will produce 74 tons per day of cleaned filasse. This estimate does not include fitting and fixing for the reasons stated above.

Table of cost, including Freight, etc.

Assuming the product to be one and-a-half tons per acre per annum on 1,000 acres, the following table will show at a glance, approximately, the price of each ton of filasse according to the cost of labour, the other figures remaining constant:—

Wages per Day.	Cutting.	Decorticating.	Degumming, including Chemicals.	Freight, including Wrapping for Bales.	Brokerage and Landing Charges.	Total Cost per Ton.
s. d.	£ s. d.	£ s. d.	£ s. d.	£ s.	s. d.	£ s. d.
0 3	1 13 9	1 4 8	2 9 0	2 10	16 10	8 14 3
0 6	3 2 5	1 19 3	2 12 10	2 10	16 10	11 1 4
1 0	5 19 9	3 8 4	3 0 7	2 10	16 10	15 15 6
1 6	8 17 1	4 17 5	3 8 6	2 10	16 10	20 9 10

The brokerage and landing charges have been taken at the sale price, £42 per ton, which sum the filasse will readily obtain in the English market. If a higher price is secured, of course this item will be increased.

Terms.

The above machinery is supplied on condition that 25 per cent. of the net profits is paid to Messrs. Macdonald, Boyle & Co., by way of royalty, and in all cases, before the machinery is supplied, the purchasers will have to enter into a contract to that effect. One-third cash is payable with the order, and the balance when the machinery is packed ready for export.

LIBERIAN IN THE STRAITS.

(*Continued from page* 216.)

Coffee Husking in London.

Some time ago I received a circular regarding the curing of parchment in London, and as it contains some valuable and useful information, I think I cannot do better than quote it in full:—

Sir,—Having been the first to erect machinery for husking coffee in London, and being frequently asked for a few particulars as to the treatment of the parchment, we venture to submit the following remarks to those of your friends who are interested in the question. At the outset we would mention that the operation is chiefly applicable to coffee treated by what is called in some countries the 'West India preparation'—*i.e.*, to 'washed' coffees, which are known by the trade here as 'coloury.' As these descriptions are much sought after by buyers, and command far higher prices than

the qualities known as 'unwashed,' it is obvious that planters in their own interests should endeavour to market their crops in the former condition, the difference in price in a normal market being fully 20*s.* to 25*s.* per cwt. in its favour.

"To obtain the best results it is necessary that each operation, commencing with the gathering of crop, should be performed with great care and discrimination. Only cherries of uniform ripeness should be plucked, as otherwise the pulping and most of the subsequent operations will be made difficult to perform, and the cleaned coffee will lack that uniformity of appearance and colour which is so highly prized by the buyers.

"The cherry coffee should be passed through the pulper (the machine for removing the pulp from the berries) as soon as possible after it is gathered, and the pulp is more easily removed before it has had sufficient time to dry and shrivel; care must be taken to see that the cherry pulp is thoroughly peeled from the berries, and as several of the latter will escape with the action of the pulpers, sieves of a size which will allow only the free parchment coffee to pass through must be used, so that the cherries remaining in the sieves may be returned to the pulping machine. After pulping, the parchment coffee has to undergo a process of fermentation, and subsequently of washing in suitable tanks, when the adhering saccharine matter is got rid of; during this latter operation it is of great importance that the parchment should be constantly stirred about, as by this means the light, black, and imperfect beans rise to the surface of the water, as well as sticks, leaves, and such like impurities, which should be skimmed off and treated separately. At no subsequent stage can this important object be attained in anything like so cheap and effective a manner as the inferior beans can only be afterwards separated by hand-picking—a tedious and costly operation.

"After washing, the parchment coffee has to be thoroughly dried—an operation requiring, perhaps, more knowledge of the article than any other, as on the way it is carried out depends to a very great extent the subsequent market value of the crop. If not sufficiently dried, the parchment becomes more or less musty in transit, and the colour deteriorates, thus seriously affecting its selling value, and from the fact that the outer layer of coffee in the bags dries on the voyage to, a greater extent than the bulk in the centre, it is impossible for us, when we dry it here before husking, to obtain an even result. In addition to this, freight and charges have to be paid on extra weight, which is an absolute loss. We may mention that many parcels we have received in a damp state have lost over 20 per cent. after drying, exclusive of the loss in weight naturally caused by the removal of the parchment. It will thus be understood that it is imperative the parchment should be properly dried, especially as extra charges are incurred for drying it here. On the other hand, care must be taken not to overdry the coffee, as otherwise the colour will be impaired to some extent, which will reduce the market value. It is, therefore, apparent that the greatest care and experience is required to ascertain when the parchment is in really prime condition. After drying, coffee intended for husking in London has only to be shipped without further loss of time.

"The advantages to be derived by planters in forwarding their coffee in parchment are several. The parchment covering acts as a great protection to the bean, while in transit, from all the deleterious influences to which it is necessarily subjected while in the close hold of steamers, on quays, etc., and above all it preserves the colour. This is probably one of the greatest advantages of any, as the finer the colour of the coffee the higher is the price paid by buyers, and it has been abundantly proved that coffee husked here fetches prices higher by several shillings a hundred-weight than the same coffee when cleaned abroad. Planters are also enabled to market their crop probably several weeks earlier than if they have to wait to husk it themselves. A material saving of labour is effected in districts where it is scarce, or where the crop is a heavy one, at a time when it is extremely important all hands should be concentrated on harvesting, and when this is complete on the more careful cultivation of the plantation, thus increasing its powers of production and at the same time getting the husking of the coffee done as cheaply as it could be effected on the estate. The outlay on machinery and other incidental expenses would be saved, and capital that would be locked up is set free. Further, the dangers of a breakdown are avoided—a very serious matter on estates, where every important piece of machinery has to be obtained some thousands of miles away. Receiving, as we do, many thousand bags of parchment coffee each year, we have necessarily obtained considerable experience in the manipulation, and are enabled to work each parcel in the way best calculated to meet the requirements of the trade in all its differ variations.

"The total cost of receiving from import ship, landing, huski sizing, and all the usual operations is 2*s.* 6*d.* per cwt., which believe is at least as cheap as it can be performed by planters, if cheaper. The charge for drying is extra, and depends entirely on condition of the parcel; but from what we have already stated, it charge which, in their own interests, planters should never incur h The loss in weight from husking varies largely according to nature of the parchment, and ranges from about 15 per cent. up t a few exceptional cases about 22 per cent. The average loss is fr 18 per cent. to 20 per cent.* The whole of the various operati are carried out in our bonded warehouses, under the immedi supervision of the officers of the Crown, which affords an import guarantee to importers that the correct weight is returned to the no customs duty is charged by the Crown authorities on the husk

"We have occasionally received parcels of coffee, dried in cherry, to husk, but we cannot recommend this mode of shipme though it is possible that in a few individual cases planters mi find it desirable to adopt it. In the first place, it adds unduly to charge for freight, the coffee never turns out of such fine colour a does if prepared as already detailed, and of course the loss in wei after removal of the cherry and parchment covering, is much heavi besides, it is much more difficult to work and necessitates a charg at least 3*s.* 9*d.* per cwt. The foregoing remarks apply solely coffee of the species of Arabia. As regards Liberian coffee, we h no hesitation in advising that, unless absolutely compelled, shipme should never be made in cherry, as this species, even under favo able circumstances, is most difficult to work.

"That the business has developed so largely since we commen operations in 1884 appears to us conclusive proof that many plant are fully alive to the benefits to be derived by the adoption of t method for marketing their crops, and we, therefore, trust th remarks may be of special interest to those who are at present unaw of the facilities to be now obtained in London, and who have suitable machinery on their estates for cleaning the coffee the selves.—We are, etc., MAJOR & FIELD, Red Lion and Three Cra Wharf, Upper Thames Street, London, E.C., March, 1892."

We pioneer planters have not had things made so easy for us: have had to find out for ourselves what kinds of machinery, pulp and peelers gave the best results, and we have had to pay very heav for our experience. The young planter of to-day has only to go to neighbour, see what kind of store he has, what kind of engine, pul and peeler, elevator, dryer, etc., and then he can go home and or the same, without risking money or time in experimenting with so more or less useless and expensive machinery.

But let me take it for granted that you have your store a machinery all complete, and that you are ready to peel. Both bef and after peeling you weigh the coffee, and you will find that in p ing you lose from 33 to 40 per cent. The peeler is a machine wh divides the bean from the husk and polishes it until it has lost thin silk skin which covers the bean. The husk and silk skin blown out at one end of the peeler, whilst the clean coffee falls throu below. To get a thoroughly good and clean sample of coffee, the par ment has to pass through the peeler as many as four or five tim Messrs. Gordon and Company, the manufacturers, themselves told that the parchment should pass only once, and that if the peelers not do the work satisfactorily in one operation, there was not suffici pressure on the beans, and more dead weight should be suspended the lever of the peeler. But my own experience has shown me t this will wear out the peeler so much quicker, and I would rath therefore, let the parchment pass through the peeler several times w less dead weight and pressure on it.

An elevator is simply a continuous chain carrying buckets wh lift the coffee from below the peeler to the store above or into a si

The sizer is a cylinder with a lot of different-sized holes, and this cylinder revolves, the coffee is dropped in at one end, and a passes through the cylinder, the small berries drop through the sn holes and the larger ones a little lower down through larger ho whilst the very large beans or pieces of wood or stones will fall ou the other end of the cylinder.

There now remain only the final picking and sorting. This is d by hand; all black and broken beans are carefully picked out, and soon as this has been done the coffee is packed in bags and shipp off to the nearest market.

* This refers to Java coffee. Liberian coffee loses in peeling about 33 to 40 per c

So far the planter has had charge of it, and he has taken good care f it, the bags have been carefully covered up, and every bit of dust as been brushed off; and the carts leave the estate with their precious oad with the planter's blessing. How sick would the planter be if he ould only see how his bags are treated the moment they have left his ersonal supervision: the cartmen throw them all in a heap at the tation, and every cooly walks over them with his dirty feet and leaves is mark on them; on board ship they are thrown down 20 to 30 feet nto the hold, sometimes bursting, their contents scattering all over he ship,—but the planter happily does not know it. And so it is with s and all that concerns us. We walk along in ignorant bliss, unaware f the dangers that await us, or have already befallen us, and it is ust as well that this be so. How would men otherwise cheerfully per- orm their work and devote all their life, health and energy to a pur- ose if they knew all the time that it was simply wasted and idly hrown away?

No. such are not the planter's thoughts when he has shipped his rop. He only feels that a great responsibility is taken off his houlders, and whether the ship goes down or his burned, it does not oncern him: his coffee is well insured, he need not trouble his mind bout that, and he does not. As far as he knows, his coffee is safely n its way to the market bound to fetch "top" prices and to make name and a reputation for him, and to lay, the foundation for enormous futurewealth. Let us hope that he won't be too greatly disappointed.

(To be continued.)

NO BUILDING BIG ENOUGH.

Probably the two women whose names we are about to mention (by heir good will and consent) never saw or even heard of each other. A road bit of sea-water rolls between the places where they severally ive. Still, the world is getting smaller every day, and it is quite possible they may meet; if they do, they will have a common subject for a talk. Without waiting for that, however, we will let the reader into the secret (so far as it is a secret) right on the spot.

The first lady to be named resides at Bishop's Norton, near Kirton, Lindsey, Lincolnshire, and in a letter dated the 16th of the blustering month of March, 1893, she says, "*I trembled from head to foot.*"

This would scarcely be worth mentioning if it had been simply the result of a fright and therefore bound to pass off in a few minutes. But it lasted for a long time and did not arise from a fright or from any other form of excitement. It meant sheer weakness and a wholesale upsetting of the nerves. "I was constantly sick and dizzy," she says, "and had a dull pain between the shoulders. I had no appetite, and the effect of what little I did eat was so bad and gave me so much distress that after a time I hardly dared touch any food or drink. During this period I may just mention that I was terribly constipated, intervals of ten days sometimes elapsing between the actions of the bowels. No laxatives or enemas availed to relieve this condition, and I became more feeble and prostrated day by day. My illness began in August, 1892, and after four months' suffering I was completely cured in December by your remedy. Indeed it was not necessary for me to take quite one bottle. If any one who reads this little statement of mine wishes to know more about my case, I will gladly answer inquiries. (Signed) Mrs. M. G. Walsham."

The second lady, writes from her home, No. 12, Horgan's Buildings, College Road, Cork, dating her letter the 27th of the sunny month of June, 1893. She says, "Everything was a trouble and a burden. For nights together I got no sleep. I couldn't bear the noise of the children. I had no desire for company; I wanted to be alone in my misery. I often thought I was going to die. I was in this way for nearly twelve months."

Now this was bad; very, very bad. When a woman cannot bear the noise of her own children—which of all noises is least observed by a mother's ear—why, her nerves are, as we might say all gone to pieces. And, inasmuch as the nerves are only a part of the body, it follows that the whole system is badly out of order. And so it was. "The complaint," she says, "came on in October, 1890." It was marked by failure of the appetite, pain and weight in the chest after eating, a sinking feeling at the pit of the stomach, biliousness, flatulency, and other signs with which the readers of these articles are so sadly familiar.

Of the progress of the malady and how low it reduced her she has already spoken. The end of it all—a happy end, thank Mercy—was like this. "In September, 1891," she adds, "my husband persuaded me to try a medicine he had heard and read so much about. I did so, and soon found relief—a relief that none of the other medicines I had used were able to give me. My lost appetite came back, and my food digested easily and strengthened me. You hardly need be told, that I continued taking the medicine, and soon I was well as ever I was in my life and have hailed nothing since. Yours truly, (Signed) Mrs. Lucy Carroll."

Women, like men, never agree on all the topics which come up in conversation. It would be a dull world if they did. But these two will agree that they were afflicted with the same complaint—indigestion and dyspepsia; and that Mother Seigel's Curative Syrup, which restored them both to health, is one of the very best friends in time of trouble that their sex ever had.

And what is more, if all the women in this kingdom who think the same were collected in one meeting, no building could be found big enough to accommodate them.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co's Weekly Coffee Report. (April 22, 1898, says:—Public sales have been on a very large scale, but in spite of this a good demand has prevailed and last week's values have been fully maintained.

About 6,500 bags East India were catalogued, and Home Trade marks attracted keen competitions, several parcels realising extreme rates, whilst medium qualities sold steadily.

Costa Rica, of which the Central American chiefly consisted, was readily disposed of at fully previous prices, but other kinds were rather slow of sale.

Futures have been steady during the week, but business has again been limited, and there is practically no change to note in quotations.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending April 20th, 1898, says:—Bank rate 4%. Bombay Exchange closes at 1s $4\frac{1}{32}$d. Brazil Exchange $5\frac{15}{16}$d. Rupee paper $3\frac{1}{2}$% $61\frac{3}{4}$. Silver $25\frac{15}{16}$d per oz.

Public sales, which were suspended for the Easter holidays on the 7th. instant, were resumed on the 14th. Since then supplies have been very heavy, importers being anxious to realize the recent large arrivals. The demand for all the better qualities has been good. and values for these have advanced 1s. to 2s., and even more for fine; the ordinary and common kinds on the other hand are barely steady, mixed Columbian and Jamaica being especially difficult of sale at a reduction of about 1s Further extensive supplies are advertised for sale, and the market will be fully supplied for some time to come.

Brazil markets are very quiet. and about unchanged.

Daily receipts averaged 10,000 bags in Rio and 11,000 bags in Santos.

Futures have been quiet and lower, showing a decline of 9d. to 1s. per cwt. since our last, viz.:—Good average Santos in Havre, May delivery, fcs. 35.25, in Hamburg pf. $28\frac{1}{4}$, and No. 7 low ordinary Rio in New York $5.85.

To-day's London official quotations are:—

	April	May	July	Sept.	Dec., '98.	Mar., '99.
Santos ...	28/3	28/3	28/9	29/3	29/9	30/3

A Circular issued by the Tea Brokers' Association states that Indian Tea importers wish sales held on Mondays only from the 1st April to the end of July, and in other months on Mondays and Thursdays; 25,000 to 30,000 packages to be offered on Monday, sales continuing until 4 o'clock, any surplus being offered on Wednesday.

Indian. The market re-opened on Monday with a sale of 22,972 packages. Bidding for all descriptions was steady, and quotations before the holidays were fully maintained with a somewhat tendency. The Official Wire from Calcutta gives exports to United dom for the first-half of April as 56,000 lbs., against 85,000 for same last year.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," 11/12, Second Line Beach, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 11 and 12, Second Line Beach, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

NOTICE.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 27th May, 1898.

Season Reports should be sent to the Printers, Messrs. Addison & Co., direct, and not to *Planting Opinion* Office.

Nilgiris.

Coonoor, 18*th May.—Weather.*—Rain so far is only just over the inch for the month, and since the 5th instant, all rain has come from the south-west quarter. High winds are only occasional in strong gusts. Temperature of course has fallen. *Crops.*—Coffee blossom is setting very well so far, and big crops are to be the rule, if all the subsequent "if's" are settled with in the right way. The long N. E. and spring drought did a great deal of damage to orchard fruit, but this is not an absorbing subject yet awhile. Tea is still "down in the month," but is showing a slight improvement. Flush worm is showing up again. *General Health.*—Health is distinctly poor; colds, fever and influenza being prevalent.

Kullakamby, 18*th May.—Weather.*—Cloudy weather and slight showers nearly every day, with strong wind. *Crops.*—Coffee looking very fair. *General Health.*—A good deal of fever about still, and general health very indifferent.

THE PURSUIT OF HOBBIES.

There are unfortunates many, we fear, who drag on a cheerless existence without the brightening influence of a single hobby. The depressing effect of a hobbyless man or woman on all his or her neighbours is well known. Work is well in its way, pleasure and amusement are good, very good. To combine both in a third pursuit ought to be the aim of every self-respecting being who will, if certain dangers are avoided, attain unto the blessedness of a hobby.

The seekers after the light must guard themselves against certain definite dangers. They must not try to hug themselves with the idea that they can make a hobby out of their pleasure or out of their business. No, business or serious work they must have, pleasure is likewise indispensable. Not to replace either, but as a crowning step to both is the proper function of a respectable and to-be-tolerated hobby.

The choice of a hobby is a most delicate matter, not to be approached too lightly, nor on the other hand with too business-like a manner. The well-balanced mind will observe a courteous familiarity with the object of his quest. He must be on his guard against gushing hobbies, he must not exhaust their possibilities all at once. That were fatal to the life of any respectable hobby. To help the beginner, we may point out certain points about a well-born hobby which no respectable individuals are without. The balance between their apparent use and the apparent pleasure they afford must not be of equal proportion. Either the pleasurable side of a hobby must be well-pronounced, or its more sober, but often more attractive usefulness must overshadow it. For hobbies exist for man and woman, and not man for hobbies. Though men often exist simply as hobbies for their friends and enemies.

There are two great classes of mankind in urgent need of hobbies,—the workers and the worked for. They do not require the same sort of hobby. A worker needs as his hobby a pursuit, the predominant quality of which is pure pleasure, as shown in its obtrusive uselessness. Its end however is pure business, like that of a wasp. A slight tinge of business must be combined in the method of the attainment of the pleasure, or the change will be too abrupt. The worked-for class, the gay and very useless butterfly, demands a higher aim of his hobby. To please his more elevated morals, his hobby must bear on its smug face the hall-mark of dull work. No outward show or gay trappings should adorn it. Its pleasurable side lies in the fact that its thorough uselessness is decorously hidden in its inmost core. For nothing renders one of the worked-for more savage than knowing that his hobby is of real use to his neighbours, for he feels deeply and justly that the fundamental law of his being has been broken.

From general laws modern philosophy descends to particulars, to point its platitudes by would-be opposite illustrations, instances that, alas, disprove its theories as often as they support them. So we shall likewise turn from the broad laws that govern hobbies to such particular cases as have come within our ken. We have known an amiable gentleman, a member of the illustrious Civil Service of India, to so chase his hobby that he died of it. If not in the fleshly body, he certainly died the death of his service. He had a pretty talent for singing the more elevated music-hall songs in the Assembly Rooms of one of our miscalled Hill Capuas. Being withal well up in the service, and renowned for the extreme solidity of his understanding, society had a wicked pleasure in applauding his efforts. He served in fact as a hobby to his neighbours. When a wandering troupe of comiques strayed out from England, the untutored minds of the station public could not appreciate their merits. For the love of stage acting, as acting, is almost a minus quantity in India. We love to act ourselves, and more to see our friends act. For the blunders of our friends are exquisitely enjoyable. But acting, except off the stage, is only attractive in India when it obviously amateur work. This our amiable friend w unable to see. He saw that his friends laughed more his jokes than they did at those of the London troupe. judged by the high standard of Anglo-India, he proved su a success, what could he not achieve on the stage England? It is bitter to record such folly, but a hobby an uncanny animal sometimes, and must be kept strictly its place. Our worthy friend resigned the service a went home. It is long years since we last heard of hi but occasional paragraphs in the *Mudshire Gazette* menti his extraordinary enthusiasm in providing comic recitatio for the good people of the Infirmary and Workhouse of t county-town.

There are other awful examples of hobbies bolting wi their owners, but we will not sadden our readers with the recital. The bright side of the picture is revealed by t extraordinary happiness achieved by Smurthwaite, of t Forest. Smurthwaite is a jungle wallah of the deepest dy and has a profound knowledge of the jargons and custo of the forest tribes. Knowing that his great failing is avoi ance of society, he has determined to do what he could counteract the similar tendency among his Irulars a Kurumbars. Of a broadly religious nature, he, havi heard of the feats of the Civil Service songster, who deplorable story we have related, obtained the loan of large collection of the most joyful and simple ballads of t Halls of English music. These he deliberately translate in Irulese and Kurumbese, bringing in happy allusions the more cheerful aspects of devil-worship. His ear f music—tunes he calls it—is not very acute, but by t help of an expensive hurdy-gurdy he gave great satisfa tion to the tribes. Some of the more popular chants ha been adopted at the public devil-rites with great effe It is curious to add that his system of brightening the liv of his tribes has received great approbation from the fe Missionaries who have heard of his work, but think h song-system is based on that of Moody and Sankey.

The space at our disposal is limited, so we cannot pursu this absorbing subject any further. We entreat, however, a readers of these pages to ponder on what we have writte For to neglect the choice of a hobby is to run the danger a hobby making of you its namesake. More important f than work or play is the pursuit of a hobby, whereby yo have a pleasurable sensation of going through the outwa movements of work, delightfully conscious of only worki at play, or playing at work.

NOTES.

A record payment for tea duty. The Mazawattee Tea Compa (Limited) claims to have paid t biggest cheque ever known in t tea trade for Customs duty, amounting to over £63,000 ste ling, and £12,500 greater than any previous amount. Th cheque represents over 1,680 tons of tea, or something li one thousand million cups of tea.

High elevation teas. Among the many disquieti features of last year's market w the sensible drop, though small, in prices for high elevati teas in both India and Ceylon. Whether the public tas is changing or not we do not know, but it has been evide

at the market lays greater stress year by year on ength and fulness. Thin pungent, flavoury liquors have len from the pride of place they once occupied.

se planting of tea.

A Nilgiri correspondent of a Northern contemporary has very ious ideas on the way tea cultivation is carried on in this trict. He states that 3 feet × 3 feet is far enough apart en in the case of the luxuriant high-class hybrid. It would interesting to see what he means by "high-class hybrids." s further remarks addressed, it should be remembered, a public composed of the first tea-planters of the world delightfully naive, and will, we trust, be appreciated.

panese tea.

It is memtioned in the report of the Yokohama Chamber of Com- erce, says the *H. and C. Mail*, that the quality of the op of tea—a great staple of the Japanese export trade— s decidedly inferior last year to that of 1896, and it is ted that Indian and Ceylon teas are now rapidly gain- g an advantage in the United States and Canada, the ef markets for Japan teas. Meanwhile the restrictive asure adopted in America, requiring the quality of the imported to be up to a certain standard, has made more reful selection necessary. On the whole, the year is said have proved fairly remunerative to the Japanese tea ower, though the attempts to introduce Japan tea into ssia have not yet met with much success.

grow "A" size coffee.

The casual reader will think this heading somewhat after the fashion the London tea merchant to his son, a young tea-planter, the effect that he was to be sure and only grow Orange koe bushes. But as a matter of fact, a great deal more ld be done to grow coffee-yielding berries of extra large e than is now imagined. It is the old, old question of improvement of our stock by the more careful selection seed. Large berries picked at haphazard from any es on the estate will certainly not give any finer or better nts. But a tree which by judicious pruning and culti- ion is encouraged to bear extra fine berries, will yield d from which in course of time a fair proportion of ig-seed" plants will be found. And, in course of time, desirable qualities of the plant may become so fixed that distinct and valuable variety would result.

drop in tea spells uin!

Such is the sensational statement recently made by a well-known visit- ing agent and merchant of Colombo th regard to Ceylon tea. A drop of another ½*d.* in prices uld mean an acreage yielding 30 million pounds of tea ing suddenly out of cultivation. For the purpose of engthening the market, such a statement is reasonable ough, but of its real truth there is much doubt. The visit- g agent in question does not think much of exchange one y or the other, arguing that a rise of 1*d.* in exchange is only ual to a fall of 3 farthings in price. This logic is rather eer, for it is obvious that with an "honest rupee" of shilling exchange value, the 4*d.* drop would equal 3*d.* rise price, which would do away with the threatened ruin of industry for some years to come. However there is no ubt that he is quite right in his contention that the whole a-trade is now almost altogether in the hands of a few yers who retail direct, and combine to keep down prices.

Laterite soils.

The South Sylhet correspondent of the *Planter* thus describes the virtues of the laterite soil of his district. In South India somewhat different opinions are held on this species of soil!

"The tea gardens of South Sylhet, for the most part, have a surface soil varying from a light sandy loam to a loam and in some cases to a distinctly clayey loam. And the subsoil, for the most part, is composed of a reddish laterite soil eminently suitable for the cultivation of tea. The fertilizing qualities of this laterite soil is so well understood by the planters in the district that in some cases pits have been dug six to eight feet deep on the sides of telahs, the bushes on which were looking scragging and giving little leaf. These telahs were top-dressed with the red subsoil from the pits with marked good effect. These remarks refer to the majority of South Sylhet gardens which, for the most part, are low telah or rolling. In some of the gardens there are large flat bheels, the top soil of which is composed of almost pure vegetable matters varying in thickness. When the subsoil of these bheels is different from the surface soil it may be composed of blue clay, or it may be white clay and sometimes white sand. The chemical reasons for the different colours of the subsoils of both bheels and telahs are very lucidly explained in any of the works of our leading agricultural chemists."

Liberian coffee.

Mr. W. Turing Mackenzie writes to the *Singapore Free Press* that while Selangor this year is to export 12,639 pikuls of Liberian coffee, for 1902 the figures are estimated at 64,533 pikuls. He adds that the East Coast of Sumatra is bound to do something considerable; but if so, how does Mr. Mackenzie explain Mr. Baker and his Dutch superiors abandoning Liberian coffee for tea, asks the *Ceylon Observer*. Says Mr. Mackenzie: "Let every one interested in Liberian coffee send home a few pounds of the fragrant bean to his sisters, his cousins and his aunts, while Straits planters should urge Ceylon tea sellers to add Straits coffee to their list; there are many old Sumatra planters in business in Europe and elsewhere who would, I should imagine, gladly take up and push the sale of *Serdang coffee*. New York is a market to be captured, but, listen. An American gentleman once came to me and asked how many pikuls of Liberian coffee I could give him. I mentioned the figure—a few hundreds. 'Cayn't you multiply that by 10?' he asked. On my intimating that my arithmetical powers did not go so far, he replied, 'Waal, sir, ef you cayn't give it us, *we must make it*.' Subsequently I made enquiries as to the manufacture of Liberian coffee in the United States. The ingredients mentioned to me did not sound as if they would yield a savoury beverage."

Wood-ashes.

We publish elsewhere an inter- esting article on the value of wood- ashes as a complete mineral manure. Not only is the potash of the ashes of high value, but the phosphoric acid present, though in smaller quantities, is not to be lost sight of. Perhaps the greatest value, however, derived from the manurial use of wood-ashes lies in their caustic effect in the inert nitrogen of the soil, a fact of striking importance in forest soil.

The value of ashes is of course dependent largely on the wood used, twigs and leaves containing a far greater pro- portion of valuable minerals than solid blocks of timber. It may not strike some of our readers with what excellent effect a system of home-made ashes might be introduced on plan- tations. The connection between disease and prunings has been somewhat energetically set forth in these columns. The greatest objection to the mode of collecting and burning

the prunings was the expense of the operation. But if the prunings were burned in selected places, and the ashes carefully gathered, the value of the latter would probably be over and above the cost of collection: Especially would this be the case on tea estates where the disposal of the prunings is often a matter of great trouble. After a few trials, it would probably pay coolies well to collect the wood and burn it on contract, being paid by the ashes, at so many annas per bushel. Care must be taken that the ashes be kept dry, as moisture greatly lessens their value.

The South American Vanilla.

At the meeting of the New York College of Pharmacy held on 18th January five papers were read on vanilla, writes a correspondent to the *Chemist and Druggist*. Professor Rusby treated of the cultivation, etc., of vanilla. He said that there are thirty-three species of vanilla now recognised. The process of curing vanilla-pods and preparing them for packing was described as he had seen it done in South America. Vanilla-packers, he mentioned, are subjected to poisoning, resulting from handling the beans, the symptoms being much like those resulting from poisoning, due, he thought, to penetration of the skin of the hand by oxalate-of-calcium crystals. Dr. S. E. Jelliffe treated of the microscopic of the subject, and said unscrupulous dealers often used benzoic acid to make a false appearance of vanillin on the beans. The microscope revealed the fraud readily, benzoic-acid crystals being flattened and rhomboidal, vanillin acicular and standing out at right angles from the surface of the fruit. Professor V. Coblentz treated of the chemistry of vanillin and said it was frequently adulterated with acetanilid. Mr. A. Henning's paper was on the commercial varieties of vanilla. He said that that from the Seychelles Islands, an inferior kind, was the sort chiefly used in England. The Mexican vanilla grown at Papantla had the most exquisite odour, and was the kind used in the United States. The pharmacy of vanilla was considered by Mr. O. Kalish, who recommended an extract made from a formula containing 8 oz., of vanilla in a gallon of finished produce. He said that vanillin could never displace vanilla as a flavouring-extract, as it lacks the delicate flavour of the natural bean.

Planting in Sumatra.

From an exchange we gather some interesting details about the way in which Dutch planters manage their tobacco plantations. It is the reverse of cheerful, though, to learn that tea is beginning to be planted up, and that its initial success is most encouraging to Sumatra planters. Mr. H. R. Porter, of Messrs. Walker and Sons, thus describes his recent visit to Sumatra:—

"His purpose was to visit the first tea estate opened up in Sumatra, belonging to the Britlsh Dehi-Langkat Tobacco Company, which owns over 35,000 acres planted with tobacco. The managers and superintendents of these tobacco plantations are, of course, Dutch; but the labourers are either Javanese or Malay coolies who understand the work well, and in contradistinction to the system in force here are individually under agreement to the planters. Labour, so far as he is aware, is plentiful, and the supervision is such as to prevent, to a large extent, desertion or crimping, it being necessary that everyone who goes off the estate, even on leave, should produce a pass to the Jagar or private policeman—and there are several of these employed by each estate—who accosts him before he is allowed to go on his way. The management of the labour force is quite different from that which obtains in India or Ceylon, there being no s persons as Kanganis, and the system seems to work very well. estate which Mr. Porter visited is the first that has been opene tea in Sumatra and is under the superintendentship of Mr. W. Ba who is a former Ceylon planter and was stationed in the Bad district before he went home and was appointed to his present bi in Sumatra. It is only two years since tea was planted on the est which was formerly covered with Liberian coffee, which has been doing very well of recent years, and tea has been doing well that orders have been issued to discontinue the cultivatio coffee and devote all attention to tea. The estate was opened tea only about a couple of years ago, and some of the bushes meas from 4 feet 6 inches to 5 feet in height and ½ to 2 inches in st The whole of the country thereabout, Mr. Porter says, seems to b volcanic origin, there being a kind of vegetable deposit on the to the lava. The elevation is not much above sea level, the estat question being about 300 feet above the level of the sea, and climate approaches very much to that of the Kelani Valley. Porter went from Colombo to Penang, thence to Sumatra in a l boat, landing at Belawan, from which he went to Medan, about 2 25 miles by rail, and then rode to Diski, and from Diski trave over 12 miles of tramway which brought him to within half a m of the estate. What tea has been made has been disposed of v well locally. The only machinery at present used is a roller, Mr. Porter's visit was to design a new factory with water-power to arrange for a complete outfit to suit the estate which is about acres in extent. This has not yet been all planted in tea, but wil as soon as possible."

The London Market.

Coffee.—At the auctions a lar quantity has been catalogued t in any previous week this season, writes the *P. M. Rev* of 23rd ultimo, and as the principal proportion has consis of East India, which this year is coming in small parc the lots have been so numerous that it has been impossi to get through the whole of the catalogues, and six h been held over until next Tuesday. Although the quan has been so heavy there has been a strong demand, a prices have, in many cases, shown some advance. Of E India kinds Mysore has sold from 1*s.* to 3*s.* dearer, many the best marks realising higher rates than those obtai last year. The finer qualities of Costa Rica have a maintained their values, and, in some cases, are rat dearer, while the lower grades have mostly sold at a sli reduction. Coffee, of this growth, from 60*s.* to 85*s.* is r relatively the cheapest kind in the market, and we think hardly likely to be lower. Of other kinds Colombian sold well at full prices. In the terminal market a moder trade has been done, and prices at first advanced, but h since reacted and closed at about last week's quotations.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain ton:—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the coming crop of seed f the parent trees of above analysis at Rs.6 per pound contai about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere s from the

MANAGER, ARIENKOW ESTATE,

Shencottai

Indian Teas.—The market opened with a good enquiry, he bidding being brisk at the public sales, with an upward endency in values for most descriptions. The demand, owever, was mainly for the more useful kinds, and in some ases the rise is quite a $\frac{1}{4}d.$, the advance being no doubt ue to the smallness of the stocks held by the trade. This ise will most likely be maintained, and will probably be llowed by a further upward movement later on, as the tock of this class of tea will prove to be none too plentiful meet requirements. Practically all the direct consign-ent of garden teas have now been disposed of; a large umber of final invoices, especially Assams, were printed nd sold this week, and therefore the future supply of the ast season's growth from this district is likely to be xceptionally small. As these kinds have throughout the eason been the most uniform in quality and, therefore, the ost desirable for blending purposes, a shortage in the pply is almost certain to lead to an improvement in prices efore long. The common and poor liquoring sorts have old at prices about on a par with those of the previous sale, nd, although an idea prevails that a higher market is robable, the heavy stock does not appear to warrant any ise of importance. The finest sorts are gradually getting nto an extremely small compass, and the few lots offered etched advanced rates, and even at the higher prices they re inferior in quality to the earlier shipments. At the ublic sales 22,972 packages were brought forward, and nly 1,450 were withdrawn.

GENERAL ARTICLES.

TEA PESTS AND BLIGHTS.

THIRD NOTICE.

Pruning.

IN our preceding article we traced Dr. Watt's initial remedial measures as far as drainage. The next chapter is on pruning. Differing conditions of soil and climate of course necessitate a great variety in the methods of pruning. Where a like diversity is seen even in the same district and on neighbouring gardens, it shows that an appreciable portion of the difference must be purely arbitrary. In Assam some managers pride themselves on pyramidal bushes, others on saucer-shaped shrubs with branches rising from not lower than two feet from the ground. The different styles of plucking in vogue have, of course, a great influence on the style of pruning. There is a large residue of difference, though that can only be theoretically justified, the clinching argument being a reference to the profits of the garden in question. We shall not follow the author in his disquisitions on the theory of pruning; his practical remarks will suffice us. Among the greatest dangers of pruning is that of causing snags on the branches, by cutting too far above a bud. The cut, where the bud is visible, as it always is in medium pruning, should be made on as close a level with the bud as possible, in a sloping upward direction. Such a cut will heal over in the season. If the cut is made too high, the stump of wood will absorb a great deal of sap at first, and then will finally die and rot perhaps even below the bud. Worse than this, in its attempts to heal over an impossible snag, the bark will swell and protrude round the base, blocking the circulation of the upward and downward sap. As sap cannot be utilised until transformed in the green leaves and green bark, it follows that a "snagged" tree is often half dead at the base while its crown seems still green and healthy, owing to the very slow movement of the downward sap.

In all intelligent horticulture outside tea-planting, efforts to determine the final shape of the plant are chiefly made while the plant is still young. There is no reason why this principle should not be observed with the tea-bush, contrary as it may be to the accepted systems in vogue. The usual method is to let the young plant run up untouched for about three years or so, and then cut them down severely to "shape the bush." This is done to thicken the central stem, and to develop the tap root. Dr. Watt questions the use of either the tap-root or the central stem. The former can be well replaced by several slanting roots, the same transformation taking place above ground. The object of the tea-planter being to produce as much flush as he can, the production of mature wood by means of a thick central stem should be hindered as far as possible. Dr. Watt urges that the first pruning should be made in the nursery itself some few months before transplanting; if not possible then, on no account should over eighteen months elapse from the date of germination. Training, and not forcing by the harsh use of the knife, is the system advocated. Naturally up to the third year or so the unpruned bush will be far taller and more vigorous looking than its trained rival. But with the first prune of the former there is a sudden reversal of the position. For the knife has, by lopping the tall seedling almost to the ground, to force the main stem to throw out those very side branches already borne by the trained nursery-pruned plants.

It is an undeniable fact that the tea-planter has to completely change the natural habit of his plant. And the sooner he does it the better. The longer the delay, the greater will be the eventual shock to the plant.

The first pruning, in the nursery, would be to head the seedling down to 12 inches, or, if only that height, to nip out the central bud. This will check the tap-root and develop side shoots. The second year's pruning consists of still further heading back the main stem and training the side shoots. The lower side branches to be retained should be headed back to the fourth bud. The higher branches should be shortened to the third bud, and the top ones to the second bud. This will open out the bush and give it a spreading habit. The third year's pruning is merely to head back the central stem again if necessary, and cut out overcrowded growth. The side branches, however,

must not be touched. This system needs undoubted care and expense, but on this initial care most of the future health and wealth of the young garden will depend. Plucking should not be dreamt of before the fourth year.

From the third year to the time that low and collar pruning is requisite, Dr. Watt finds little to criticize in the methods current in Assam. But on collar pruning he has some remarks to make. With a large majority of plants there is a certain point known as the collar, which strictly defines the boundaries of the stem and the roots. With tea, however, roots are often just as capable in producing shoots as the stems and branches themselves, so that the fear of "going below the collar" andthus killing the tea bush is not based in fact. The usual system is when the bush is incapable of producing vigorous shoots, to cut the stem back so as to leave from 1 to 12 inches of stump above ground. From reasons already given our author is strongly against such a premium being laid upon the formation of snags, and encumbrance of old and useless wood. If collar pruning is to be undertaken at all, let it be done thoroughly. Cut the stem a couple of inches below the stem of the ground, and immediately earth over. Fresh shoots will spring up from the roots themselves and will be from the first in direct connection with their food channels, instead of having their supplies stopped and diminished by passing through old and useless wood.

THE ACTION OF MINERAL MANURES.

The value of certain forms of even the same manure differs greatly according to the soil and climatic conditions. Thus, bone meal, for instance, gives the best results in soils rich in organic matter, but poor in carbonate of lime. For the presence of much lime hinders the decomposition of the bone dust, as the solvents of the soil act more readily on lime than on phosphates. The custom of applying such organic manures as oil-cake with the bone-dust is justified by the acids evolved in decomposition acting quickly on the bones. Writing to the *Ceylon Observer*, Mr. M. Cochran, the Colombo City Analyst, remarks that the "complete nitrification of four parts of nitrogen produces 18 parts of nitric acid, which, if saturated with lime from the bone phosphate, would remove therefrom eight parts of lime, changing part of the phosphoric acid into more soluble forms. In like manner, the nitrogen of the oil-cakes by nitrification reacts on the bone meal. We thus find that the subject of nitrification, besides having a direct interest as nature's method of rendering organic nitrogen fit for plant food, has also a collateral interest, as assisting in the process of rendering the more stable phosphates, such as bone-phosphate, available for plant food. It is interesting, therefore, to note the results of some experiments, on a small scale, published by Ph. Boname on the rate of nitrification of the organic matter in a typical soil of Mauritius, and of certain nitrogenous manures, all of which are used in our Ceylon tea-soil. The Mauritius soil is rich in nitrogen, and poor in lime, and the climate favourable to nitrification. In the unmanured soil, nitrification was greatly promoted by an addition of carbonate of lime, and still more so by caustic lime. The nitrogenous manures experimented with were sulphate of ammonia, dried blood, oil-cake and fish guano; and the result of a series of experiments, without addition of carbonate of lime or lime, showed that fish guan nitrified the most readily, then cake, then dried blood, an last of all, sulphate of ammonia, which nitrified very slowl The rapid nitrification of fish guano explains why tea re ponds so readily to this manure. Boname remarks th 'probably nitrification is assisted by the presence of calciu phosphate and carbonate in the organic manures.' Ce tainly, when chalk was added along with the nitrogenou manure nitrification was hastened in every case, the ord of nitrification being then sulphate of ammonia, dried bloo oil-cake, no experiment with fish guano being recorde I note, however, that in this experiment the chalk wa added in very large proportion, viz., 5 per cent. of the soi The slow nitrification of sulphate of ammonia in the absen of carbonate of lime, and the beneficial results obtained b its application to crops, are regarded by Boname as sup porting the view that, under some conditions, plants ca directly utilise salts of ammonia. Seeing then that lim or carbonate of lime hastens nitrification, and liberate potash, an explanation seems to be required why th general experience of tea planters is unfavourable the liming of tea soils. The only chemical reason whic suggests itself to me is that, by liming, the available phos phoric acid is not increased *pari passu* with the potash an nitrogen. Little, therefore, of the extra potash will b utilised, and much of the nitrogen wasted as, when nitr gen has been turned into nitrate of calcium, it percolate through the soil gradually and is lost with the drainag water. Mr. Baur, whose articles on manuring have bee read with much interest, is quite correct in his view tha by the use of phosphate and of potash in readily availab forms the proportion of nitrogen in manures may be re duced. This may be regarded as a general principle i manuring; and, now that soluble phosphates and salts o potash have been brought within reach of the planter, ought to be made matter of experiment how far the genera principle enunciated is applicable to a perennial leaf-cro like tea. Several of the experiments with Thomas' phos phate powder suggested in the pamphlet published b Messrs. Freudenburg and Co. have this for their object, t see how far the nitrogen in tea manures may be reduce by the use of Thomas' phosphate powder and sulphate o potash; thus, four of the experimental mixtures contai each only about two-thirds of the amount of nitrogen con monly used; one contains only one-third of the amoun and one contains no nitrogen at all.

"Mr. Baur's fertilizers for tea supply phosphoric acid i a different, but very available form, together with salts o potash; and, although the nitrogen is in much smaller pro portion than in the tea manures commonly used, it i nevertheless, greater in amount than in the manure recommended and used with success for cereals, whic take up fully as much nitrogen from the soil as averag crops of tea. The great advantage of phosphates solub in water is their initial diffusibility through the soil. The gradually relapse into the less soluble forms, but in a ver fine state of division, readily acted upon by the acids of th root fibres or hairs. I might cite one instance whic appears to me to tell in favour of using more availabl phosphatic manure than bone meal, together with a reduc tion in the proportion of nitrogen in manures. A sho time ago I had a soil to analyse from a very fertile te estate, yielding in years of good rainfall over 1,000 lb. dr

per acre. I naturally expected to find this soil very
n in nitrogen; but, on the contrary, the nitrogen was
rcely of average amount; but the soil was rich in phos-
oric acid and potash. The soil was a fine red soil, con-
ning a good deal of oxide of iron and alumina; and,
nough the soil was in a fine state of division, it allowed
ter to percolate through it with sufficient freedom to
ure very good aëration. It was a soil evidently well
ed to ultilise the natural supplies of nterogen."

LIBERIAN IN THE STRAITS.

(*Concluded from page 229.*)

nters' Associ-tions. As it was with the bundle of sticks, so it is with the planters: as long as they keep together, the Planters' Association as one body will be strong; moment Government has to deal with each planter individually, planter will be nowhere. But it would be quite a mistake to ge from the foregoing remarks that I advocate the formation of a nters' Association for the sole object of defending their rights inst Government. No; the chief object of a Planters' Association, ording to my humble opinion, is to enable the young planter to that support, advice and assistance which he is so much in want and to achieve by united efforts what one alone would never be e to carry out.

f the planters would put their capital together and start one ing establishment. where the crop of all the members could be ed where each member could get his parchment peeled at a rate ich would just cover expenses, they would show to everybody at united strength could do, and they might even make the estab-ment pay handsomely by curing the crops of those who are not mbers of the Association at a higher rate—this would also, at same time, show each member the advantage of belonging to the sociation; but they won't do it. They prefer to erect their own arate establishment and to pay $10,000 each, where united they ld do it at a cost to each of perhaps one thousand only.

f the planters would unite and use their united influence they ld start a bank to advance money to deserving young planters; y would by doing this render a great service to many a young ow who must go to the wall now simply because he cannot raise a dollars at a time when he needs them, although his property may worth ever so much. Up to this present moment there is no nce for a planter in the Native States to raise a cent on his pro-ty. If they would do something of the kind they could make it very well indeed, without running the slightest risk, and also der to the State a great service by saving many a promising planta-n, which is now bound to be ruined and to be abandoned; but y won't do it. They let each poor fellow paddle his own canoe, if he capsizes and stretches out his hand in despair for some one save him, offers all he possesses—all his money, all his property y to save him from ruin—they won't do it. He may die and ish!

There are hundreds and thousands of things which the Planters' sociation could do; but they don't do them.

There are a few members who look upon the Association as their n "show," disregard rules and regulations when it suits them and tack others when they open their mouth to speak for the benefit of e planting community. The majority of the members don't take fficient interest in their own affairs to take any active part in any cussion. Others are sound and useful men, at least they could be d might be; but as one of them said to me, "I dare not get up d speak out of fear that the fellows would laugh at me." Others nsider the Association the means of improving their social position, meet all the big planters on equal terms and afterwards have tiffin th them. Others think this a splendid chance to worry and to noy Government about everything, and to say and to do spiteful ings under cover of the Association, which they would never dare say on their own responsibility.

But because the Planters' Association has not yet done any great ngs, it is no reason why it should not do them in the future, and it uld be a great mistake to look on the Association disparagingly for any young planter to keep out of it.

Every planter should join the Association, and Government should courage it in every way. The Association may be able to render very valuable services to the Government, and one great service the Association has already rendered to the State—it has advertised the place. All the new planters who have lately come to the State and taken up land in Selangor have been attracted, not by any liberal terms offered by the Government, but simply and solely by the trumpet blown by the Selangor Planters' Association.

Government. Besides the many accomplishments which a planter must possess to make the cultivation of coffee a well-paying concern and a success, he has to depend to a great extent upon circumstances which are entirely beyond his control.

The selection of the soil may be his own (even the richest of soil requires all the planter's skill and care after a couple of years), but he can't rule the weather. Neither can he command the Government to render him such assistance and encouragement as he may think are necessary to make his enterprise a success. Of course, having like a careful planter selected his own land, he will not start planting in a district where the Governor, or the Resident, or the District Officer throws obstacles in his way; but Governors, Residents, and District Officers don't stay for ever in the same place, and in the last few years we have seen several different Governors and new Residents, and, as far as the District Officers are concerned, they seem to have been changed almost every week.

It has often been a puzzle to me how a district or a State can flourish where every official, as soon as he begins to know his district and the people a little, is replaced by a new man, fresh to the place, and who often distinguishes himself by reversing everything his predecessor has done. The secret of the success of the Native States must be in the stability of their inhabitants—that is, mainly the planters, and as long as they remain it does not matter how often the direction of Government is placed in fresh hands.

The interests of both the planters and the Government go hand-in-hand, and where the Government find it to their interest to encourage and to assist the planter, they do it. Be it therefore said, the Government of Selangor and others of the Malay Peninsula consider it to their interest to encourage planting, and they have always done so; in days gone by they have given great financial assistance to planters, and have, I believe, in many cases experienced some difficulty in recovering their capital or even interest. Yet the planters are not satisfied, but are always at loggerheads with the Government. It is the same everywhere.

But in justice to our Government let it be acknowledged that it is a fair, just and liberal Government—a model Government compared with others. In Sumatra, for instance, the planters are under Dutch Government, which draws millions of dollars of revenue out of the country and the planters; but the Government does nothing, and has done nothing, for either.

Here we have good roads, good courts, police and every protection; transfer of land or other transactions are effected without any delay; you can meet the Government officials in their offices during business hours; Government has provided a Rest House in every district, and if a planter wants to see his District Officer, he need not be afraid of having to sleep like a beast in a stable, Government has provided a decently furnished house for him, and the planter has only to come to find everything that is necessary to make him feel comfortable and at home.

Further, the Government has provided qualified dressers and certified medical men, and in every district there are excellent hospitals, well kept and well managed, all at the expense of the Government—and these advantages the planter gets for nothing, gets it free from a Government which as yet has not derived any benefit from planting, but which with wise foresight does all this to attract and encourage planters, well knowing that agriculture will open up the land and that any capital spent in encouraging planters to settle in the State will not be wasted or thrown away, but will ultimately prove a good investment aud bear good interest to Government.

Government! It is such a nice expression, it is such a convenient word: we say "Government" in the same way that we say "Providence"—there is a power, we know it exists and we see the figures move, but the man who pulls the wires sits behind the scene and is beyond our ken. Who and what and where is this Government? The Government is the owner of the State, all officials are only the servants of that Government! the Government of our little State is under the Governor of the Straits Settlements, but the Governor, S.S. says he can only advise the Government of H.H. the Sultan, and the Governor again is only the servant of the

Government and gets his orders and instructions from "Home" and the Government at home—well, look here, I give it up! If you want to kick the Government, you will find it a very difficult matter to locate its body. Therefore, always try the other thing; if you want to praise the Government you will never have any difficulty in finding one who is willing to take the responsibility upon himself, and if the State has gone ahead and flourishes through agriculture —well, the planters have not done it: it has been done through the wise policy of the Secretary of State, the liberal and generous Government of H.E. the Governor, the encouragement given and sympathy shown to the planters and tact and diplomacy exhibited by the Resident, the justice and fairness shown by the District Officers, the untiring zeal displayed by the Commissioner of Lands. At the same time, let it be understood that the Government consists of human beings like ourselves, some of them with more brains and less "frills" than ourselves, others again with a maximum of "frills" and a minimum of brains: but, on the whole, a lot of unprejudiced, fair-minded, honest, straightforward gentlemen; and I must give them the honour that is due to them, that whatever they do, they do it with an honest intention, working hard to the best of their conviction for the welfare of the Government entrusted to them—but they are weak, human beings like ourselves, and they are liable to make mistakes. One official will follow one system and another will follow another. It is the same with us planters; we may work hard for years and only find out our mistake when the coffee fails to give us the return which we expected; we did our level best, but we made mistakes because we did not know any better, and thought that what we did was the right thing to do. It is so with the Government. One Governor will think it a wise policy to give planters as much land as they want on liberal terms; another will think it right that they should only get 320 acres and that they should have to buy it by public auction at an upset price and a premium. One Governor will give the planters medical assistance free; another will force them to keep their own hospitals, dispensaries and doctors. One Governor will carefully abstain from interfering between the planters and their coolies; another will pass rules and regulations for the better protection of both parties—whether either wants it or not has nothing to do with it. One Government official will think that he is there to assist the people in every way and consider himself in the service of the public; another, again, may consider himself the ruler of the people, placed there by Government and providence to represent Royalty and God Almighty himself, and to keep us in order and to see that we pay our respects and our taxes regularly to our Government in heaven and on earth, and to watch that all rights and privileges are reserved for future generations, and nothing for the living people, who are so selfish as to expect something for themselves.

One official may think it a good policy to give us a voice in matters concerning our own interests and the State we live in; another may think that it would only lead to confusion to grant us any political rights (such demands are only supported by Jameson in the Transvaal); and so far the result has shown that, although we have no voice in our Government, not even in electing our own municipality or even the President of our own Club, the State has gone ahead, and everybody seems to be happy and satisfied under the rule and protection of Government, and if planting is not a success in this country, it will not be the fault of "our" Government, which is only too anxious to encourage planters to settle here and to give them every reasonable assistance.

WAR AND PLANTERS: CINCHONA.

WHAT is the probable effect of war on home and foreign trade? asks the *Chemist and Druggist*, and then replies to its own question as follows:—"Prices will go up," makes the easiest reply; but it is a remarkable fact that the produce-markets have so far been little affected by the belligerent attitudes of Spain and the United States. Affected, that is, as regards upward movements in prices. Wheat is practically the only article which has been visibly affected in that way; nearly everything else has been at a standstill, and for the moment there is no sign of abnormal activity. For actual stagnation of trade in the first hands there is nothing so effectual as rumours of war, which are positively worse from a commercial point of view than war itself. War is costly, wasteful, ruinous; b unquestionably makes business hum—creates a legitimate de for some articles, and a speculative one for others. It acts o body commercial like alcohol on the body physical. Quinine i recognised war-chemical. During the past seven days the alk has been growing steadily stronger. Second-hand sellers hav manufacturers' prices and the market closes firm. The impre is that the prospect of war warrants the second-hand activity. quinine will be dearer is almost certain, but whether it will be dearer depends on the course the war takes. If United States' t are landed in Cuba they will require enormous supplies of qui General Weyler has told us that fever will kill half of the U States men, and he will be responsible for the rest. Quinine fair example of many articles, unconnected or connected dir with Spain and the United States, which are pretty sure to go h in war. Assuming that war takes place, and Cuba is the centre not many Spanish commodities which druggists are intereste will be affected. Saffron is the most important. But there many United States products which already show signs of ri Cascara sagrada and peppermint oil are amongst the heavie them, and they are being quietly bought up at good values. fornian honey, senega, serpentary, podophyllum, and other Ame roots, as well as many South American drugs which we get *viâ* York, will be in shorter supply towards the end of the year, i United States makes an army of the poor labourers who devote lives to the collection and distribution of such articles. Immed scarcity is not anticipated, because the carrying-trade betwee United States and Europe is chiefly by British vessels, and it is that our Government will secure the freedom of the British flag, although Spain and the United States are not parties to the i national agreement which protects the vessels of non-bellige nations. Both the United States and Spain are bound to be custo of this country for what may be called emergency-goods. former has a vastly greater manufacturing capacity than it had i time of the Civil War, so that no conclusive inference can be d from the experience of that epoch. Then both of the combat were immense buyers, and not a little proportion of the purch was sunk in the sea in the endeavour to get them into Charles Speculators lost their money, but producers reaped profit all same. Surgical instruments, lint, and antiseptic dressings among the leading sundries which will be in demand as soon as commences, and English manufacturers will share in the or Chloroform, morphia, portable foods, and other articles which ca readily thought of will come into exceptional demand and both s will require them. It is not pleasant to think that we are to be by the cruel struggle which seems bound to result, butit is at better than suffering by it.

WOOD-ASHES.

EVERY intelligent gardener knows the value of wood-ashes fertiliser, and until a comparatively recent period wood-ashes really almost the only commercial manure that was procurabl America, artificial manures not having come into use in that cou But it is somewhat remarkable that the value of wood-ashes and beneficial results of their application to the soil are gene attributed solely to the potash which they contain. Undoubt potash is an indispensable food for plants, and its applicatio crops is usually marked by conspicuous results. Those garde however, who have had long experience with potash in the for wood-ashes, and also as potash salts or kainit, find that the latt not so marked in its effects as the former. The fact is, tha recently remarked by Mr. S. Macon in the *American Agricultu* wood-ashes are really a mixed fertiliser, and a complete one s as the mineral elements of plant-food are concerned. This mus apparent to anyone who considers that they are the whole res of plants after being burned except that part which returns to atmosphere from which it was originally procured.

The nitrogen and the carbon of trees alone are thus wantin the ashes, which contain everything else required by plants. T it is only reasonable to infer that the benefit derived from a dres of wood-ashes to any crop must be due to the other element well as to the potash.

[w. 15-11-98.]

Of course, the value of ashes may vary considerably according to eir source, though practically this variation is less than would be pposed at first sight. Ashes are richer or poorer in potash and her useful ingredients according to the kinds of plants from which ey are obtained, and to the character of the soil on which the ants grew. Also it is found that the value of the ash varies cording to the parts of the plant that have been burned. The hes of twigs (faggots for example) would always be worth more r horticultural purposes than the ashes of heart-wood taken from e middle of an old tree: and in general the smaller and younger e wood burned the better the ashes.

Taking what is known of the composition of the ashes from young igs and that from heart-wood which has fully matured, one would y that the proportion of potash in ashes may vary from 5 to 20 r cent. But a much better criterion of the real composition of hes is afforded by the experience of potash manufacturers, according whom a bushel of wood-ashes weighs about 48lb. on the average, d yields rather more than 4lb. of potash salts. Professor Storer s investigated this question somewhat in detail, and was found the analyses of a number of samples of wood-ashes that selected ecimens contain $8\frac{1}{2}$ per cent. of real potash and 2 per cent. of osphoric acid; or say $4\frac{1}{2}$lb. of potash and 1lb. of phosphoric acid r bushel of ashes. Hence there is enough potash and phosphoric id to make the bushel of wood-ashes worth from 10*d.* to 12*d.*, and sides that, some 5*d.* to 7*d.* additional may be allowed for the alkali power" of the ashes. This may be explained as the force of kalinity which enables wood-ashes to assist in the rotting of weeds nd to ferment peat.

[The average percentage composition of 25 descriptions of trees 5·5 per cent of potash, 34·3 of lime, 1·9 of phosphoric acid.]

The barks of trees are still more rich in lime than in potash than the above percentages. And as all plants contain lime, this ement of the ashes should be taken into account, as well as the her ingredient, for it is known that the production of nitrogenous ant-food goes on most easily in soils that have a considerable roportion of lime in them. Indeed, it may be said that this supply lime is indispensable to the action of the nitrification bacteria, hich must have lime within reach for its proper development.

ACTION OF POTASH ON SOIL-NITROGEN.

An objection is sometimes made to wood-ashes as a manure for orticultural purposes that the plants to which they are applied row coarse. This may be due to the nitrogen supplied to the plant the action of the potash on the humus of the soil. This power of otash to make the nitrogen of the soil available for plants is a luable one, and is strikingly shown in clearing wooded localities. or wherever a heap of wood and scrub is burned, it is noticed that egetation afterwards is apt to be particularly rank and luxuriant recisely where the largest quantities of ashes are lying. This nkness of growth is doubtless to be attributed first to a super-undant supply of nitrogenous food brought into activity by the d of the ashes, though it is believed that the spots charged with kali from the ashes are in many cases better supplied with oisture by capillary action than the surrounding portions of round.—*Gardeners' Chronicle.*

DISTRICT ASSOCIATIONS.

SHEVAROYS.

PROCEEDINGS of the Monthly Committee Meeting of the Shevaroy lanters' Association held in the Victoria Rooms, Yercaud, on Monday, e 2nd May, 1898.

PRESENT:—Revs. J. M. Kempf, M. Andersen, Messrs. J. C. Large, . Rahm, S. M. Hight, C. G. Lechler (*Chairman*), R. Gompertz (*Honorary Secretary*).

1. *Read* Notice calling the meeting.

2. *Read* letter from Mr. Sice resigning his seat on the Committee nd his Membership of the Association.

Resolved that Messrs. J. H. Short and H. B. Evans be invited to rve on the Committee in lieu of Mr. Sice and Mr. Leeming, who ave resigned.

3. *Read* Correspondence *re* supply bills and the stoppage of ncashment of currency notes.

Resolved that the Honorary Secretary be requested to write and ggest that as Government object to charge a commission on cash-g currency notes, the Accountant-General be requested to issue supply bills of Rs.100, 200 and higher denominations to the Deputy Tahsildar of Yercaud and empower him to sell them for notes on payment of 1/8 per cent. commission: and that if this cannot be conceded, he be requested to empower all Treasury Deputy Collectors to issue the supply bills to meet the case of those planters who get their money from Coimbatore, Calicut, etc., etc.

4. *Read* letter from Agent and Manager of the Madras Railway agreeing to stop the mail trains at Kadiyampatti in compliance with Honorary Secretary's request, and Honorary Secretary's letter to him conveying the best thanks of the Association for his action and promptitude.—*Recorded with satisfaction.*

5. *Read* letter from the Secretary, U.P.A.S.I., asking us to nominate witnesses before the Currency Commission and Honorary Secretary's reply nominating Mr. Leeming.

Resolved that the Honorary Secretary be requested to submit the name of Mr. H. Gompertz to the Secretary, U.P.A.S.I., as one of the witnesses before the Currency Committee.

6. *Read* Circular from the D. A. G. M. to Chairman of the U.P. A. S. I., enquiring if he could raise subscriptions for a shooting match to be called the Coffee Planters' Stakes, or any other name preferred, to be shot off at the next meeting of the Southern India Rifle Association.

Resolved that the Honorary Secretary be requested to circulate the letter and to invite subscriptions.

7. *Read* and *Recorded* letter from Secretary, U.P.A.S.I., *re* the Ladybird scheme and expenditure thereon up to 21st April, 1898.

Read and *Recorded* letter from the Secretary, U.P.A.S.I., asking us to approve of the action taken by the Chairman in regard to the Currency question and Honorary Secretary's reply thereto approved and confirmed.

8. *Read* letter from Superintendent, Police, demanding payment of Rs.18-8-3 for special constables employed to prevent coffee stealing till the 15th instant.—*Recorded.*

C. G. LECHLER,
Chairman.
ROBERT GOMPERTZ,
Honorary Secretary.

NILGIRI.

AT the Annual General Meeting of this Association, held in Ootacamund on Friday, the 13th instant, the following members were present:—Messrs. E. G. Windle (*Honorary Secretary*), W. L. Edmiston, J. Stanes, J. H. Roscoe, L. W. Gray, J. H. Wilbraham, D. W. G. Cowie, G. Romilly, Aboo Mohommed Sait and two others.

Mr. J. Stanes was called to the chair.

The two most interesting items on the Agenda were, says the *Madras Mail*, the reading of the Honorary Secretary's report for 1897 on the work of the Association during that year, and the perusal of the correspondence connected with the Currency question. On the latter, by invitation of the Honorary Secretary, Mr. Romilly made a speech, which is appended.

The following report by Mr. Windle for 1897 was adopted:—

CHAIRMAN AND GENTLEMEN,—I have now to place before you the Annual Report for 1897. At the end of 1896, the number of members was 68; during the past year we lost 6 of these, 3 resigned, 2 left the district and 1 died, leaving 62, but 12 new members having joined during the year, our members now amount to 74. The Association accounts show income amounting to Rs. 5,369-3 and expenditure amounting to Rs.4,801-6. If the general expenses should appear large, I would remind the Association that including the various funds which were started during the year more than $2\frac{1}{2}$ times as much money was collected as was the case in 1896, and consequently there was a considerable increase in expenditure on printing, postage, &c. The accounts have been audited by Messrs. Deane and Morgan and are laid on the table. During the past year, the Report of the Committee of Enquiry was issued and referred by the Madras Government to the U.P.A.S.I. for consideration. In deference to the wishes of Government, this was done in Committee and the Report was returned on the 13th August with a letter embodying the views of the U.P.A. We now await such action as Government may be pleased to take in the matter. The proceedings of the U.P.A. were fully reported at our meeting held on the 26th November, 1897; it is, therefore, unnecessary to review them again, but the results of some of these proceedings should be placed on record.

Mr. Newport has been despatched to Australia, where he has been engaged in collecting ladybirds which attack green bug and other scale pests. The scheme for getting an Agricultural Chemist for planters has fallen through, for the present, owing to divided interests, but indirectly some good has been done. One firm of curers has, I understand, obtained the services of an Assistant trained to analyse, and another firm took advantage of an Assistant's holiday in England to have him also put through a course of analysis. The Mysore Government has held out some prospect of employing a competent analyst, who would be more or less at the service of planters, and it may be said that planting public opinion has been fairly roused to the importance of scientific help. But if real good is to result, it must be recognised that the planters' interests cannot suffer by an attempt to divide or link them with those of a firm or of a Government in such a matter. Regarding the experiment of endeavouring to import labour from famine districts, it can only be said to have proved a failure; the immediate cause being the rain which fell after the gangs had been collected and which enabled them to get work in their own districts. A useful concession to planters amongst other cultivators is the abolishing the necessity of upkeep of internal boundary stones, where adjoining fields are similarly assessed. The season for coffee has been, on the whole, an excellent one, as far as yield is concerned, if we except the Western slopes. In several cases estates gave higher yields than they have ever done, and outturn from the cherry was good also, whilst parchment ran about the average. These favourable circumstances, however, were largely discounted by the heavy fall in prices caused by overproduction in South America; the fall in the case of coffee amounting to from £30 to £40 per ton, and the rise in exchange which we are now suffering from. The result is that cultivation expenses are everywhere being reduced, which in turn must react upon crops. Leaf disease was not nearly as troublesome as in the previous year and scale pests were also better.

The calendar year 1897 cannot be said to have been a favourable one for tea planters. The rainfall generally speaking was up to the average of the Hills, but the average number of rainy days was fewer than in 1896. The almost total failure of the N.E. rains prevented estimates, in many cases, being realised. In other products the high rate of exchange and low prices in Mincing Lane operated prejudicially. Really "standing out" teas always appear to fetch full value, but the large quantities of what may be termed "medium" teas from some of the N. India Districts, as well as from the low country in Ceylon, where heavy yields and low cost of production are aimed at rather than teas with character, have brought this class of tea to what, it is hoped, may be the lowest price it will reach. Nilgiri producers should congratulate themselves on being able to dispose of a certain amount of their produce in India, and should endeavour to extend their sales, more especially in the Bombay Presidency. It must be noticed with regret that some high-grown teas from this district have been sold in the London market at very low average rates per pound. This must not only be a loss to the producers, but is calculated to bring Nilgiri teas into contempt in Mincing Lane, and while not in any way wishing to interfere with private individuals in the management of their own estates, there is an absolute necessity for tea proprietors not only keeping up to date in the equipment of their factories, but also of giving their managers ample withering accommodation which in many cases is lamentably deficient, so that Nilgiri tea must be looked on by brokers and buyers as of the "stand out" order rather than the "medium" type, a position in which they once became classed and which it will be no easy matter to raise them from. From the elevation they (Nilgiri teas) are grown at, the climate and the nature of the soil, the teas from this district are entitled to rank amongst best growths, but these natural advantages are of little avail if not backed up by adequate withering room, proper factory arrangements, and, we might add, constant and competent European supervision.

The thanks of the Association are due to the Police authorities for the trouble and care taken during the coffee season to prevent thefts, the district being very effectually watched. Our various Collectors have also individually earned our thanks, though it must be obvious that the keleidoscopic changes of officials, which occur in this and the Coimbatore District, cannot tend to a continuous and rapid despatch of business.

In conclusion, I beg to place my resignation with that of the Committee in your hands.

On the Currency question Mr. Romilly spoke as follows:—

CHAIRMAN AND GENTLEMEN,—Your Honorary Secretary has very kindly given me permission to address you to-day in my capac of Chairman of the U.P.A.S.I. on the subject of the Curre question and the steps that I have taken on your behalf with reg to it. I will, therefore, give you a short *résumé* of what has tal place during the current year. In January, as you know, the co tion of the money market was intolerable, and such of you as n have had to borrow will know that it was an uncommonly diffic task, and money was unobtainable except on the very best secur and even then at extortionate rates. It was felt, on all sides, t the present policy of Government was doing harm to trade, and Madras Chamber of Commerce addressed the Government of In on the subject and advocated as a remedy the adoption of what called the Lindsay Scheme, whereby the exchange value of the ru will be fixed. On reading this I thought it my duty to protest once on behalf of the producers. There was no time for delay or refrence to the Committee, so on my own responsibility I addres a letter to the Finance Minister protesting against a fixed ru and suggesting that the true solution of the difficulty was the opening of the Mints, and that Government should recoup the selves for their own losses in so doing by imposing a direct exp duty on produce. This letter elicited a singularly petulant a weak criticism given in the columns of the *Madras Mail* by one w was called by the Editor an acknowledged authority on Ind Finance. Now, this authority showed that he had completely mis the whole point of the case by saying that some industries, such sugar, could not stand an export tax, oblivious of the fact that already was taxed and that we were asking for a diminution inste of an increase in the tax. In fact I think that the *Madras Mail* c not treat us with its usual courtesy in publishing such a criticis written not in a judicial spirit, but with all the rancour of partisansh

Later on, in March, the Bombay Chamber of Commerce in a ve excellent letter, as I thought, also addressed the Finance Minis and suggested a Commission of Enquiry before anything furth was done. As soon as I saw that this Commission was to appointed, I at once wired to Calcutta asking that our views mig be represented before the Commission, and an answer came ba that our letter of the 4th February had been sent to the Secreta of State, and asking if we wanted further representation witnesses. At that time a public meeting of all classes was he in Colombo to protest also against the present Currency policy India, and the result of it was that the Ceylon Government wir Home asking that Mr. Christie might be allowed to represe Ceylon as a member of the Commission. I then wired to Sim asking that Mr. Acworth might be allowed to represent us either a member, or at any rate to give evidence, but I am sorry to s that although, presumably, Mr. Christie and Mr. Acworth will allowed to give evidence, neither of them has been nominated as member of the Commission. I am the more sorry for this, for far as I know there is no one on the Commission interested sole in the growing of produce. Sir J. Muir, doubtless, represents very big tea interest, but then he also has many other interests his own to look after. I am sorry that the Commission is not ma up more largely of unbiassed experts, for when a question of th sort arises which affects the individual pocket, it seems impossib to prevent self-interest affecting the judgment, as is shown by t recent proposals put forward by the Government of India, whi entirely ignores all other interests but its own. After all, all th we want is justice and a fair hearing, and I do believe that at lea we are likely to get this latter. After we had nominated Mr. Acwor as our representative, we received a telegram from a Capta Marriott in Simla, who said that he coincided in our views that t Mints should be opened, and an export tax if necessary impose and that he was willing to go Home and represent us. But havi already nominated Mr. Acworth, I declined his offer with thanks.

In my letter to Mr. Acworth, I have given him a perfectly fre hand, but I have suggested that if he finds that it is useless to urg the reopening of the Mints, as it would seem to be from the utte ances of Lord George Hamilton and Sir James Westland, he shou try to effect a compromise, and if the rupee is fixed in its exchan value, it should be fixed at the rate now ruling in Japan and t Straits, which is at 1 shilling. I am glad to see in the papers th Sir D. Barbour also advocated that the rupee should be allowed drop nearer to its true value before being fixed. I have also urge on Mr. Acworth that he should work in union with Mr. Christ of Ceylon. The Ceylon Planters' Association in answer to ou circular said that, as the Ceylon Government was not in financi difficulty, the question of an export tax did not affect them. But

e made it quite clear to Mr. Acworth that we do not want to ndicap the Indian tea trade with an export duty in favour of rlon, as, though, at the present moment, we are both heavily taxed, we are competing on terms of equality. Some suggestions have ely been made to me by means of the Committee, which I have not ed upon, partly because I think them unnecessary, and partly ause they came too late. One was that we should urge on Gov- ment and take evidence among planters out here on Commission. t as we have a number of able planters at Home whose names I e sent to Mr. Acworth, we should be able to prove our case, and, reover, I doubt the policy of making a request which would pro- ly be refused. Another suggestion was that a Committee in ndon to watch our interests be appointed, but as I had already en a free hand to Mr. Acworth, I did not consider it wise to go k on my previous instructions. You will easily understand that oughout these transactions there has been no time for hesitation l, in consequence, I have had to act entirely on my own responsi- ty even to the extent of committing the U.P.A.S.I. to consider- e expense without sanction of the Committee. I know that it is possible to please every one, especially in a difficult matter like s, but I can only trust that my action will have met with the ap- val of the majority of District Associations and of the general ly of individual planters.

I should like here to testify to the very valuable assistance that I ve received, throughout these negotiations, from our energetic cretary, Mr. Ormerod.

A vote of confidence in Mr. Acworth as the Planters' representative the London Currency Commision was asked for and recorded.

Messrs. Edmiston and Windle were elected delegates to the next nual meeting of the U.P.A.S.I. at Bangalore, while on the posal of Mr. Edmiston, seconded by Mr. Wilbraham, Mr. Windle s nominated Honorary Secretary for the current year, an office ich he notified his willingness to accept. It was resolved to quest the present Committee to continue in office during 1898, h the exception of one member, who had during the year sold his ate and hence was no longer a planter, and the addition of ssrs. Bell and J. Stanes on the proposal of Mr. Edmiston.

The Association resolved not to take any action on Mr. Kindersley's position for the registration of small native estates and crops, d on the Hon'ble Mr. H. P. Hodgson's suggestion, it did not feel led upon to express any opinion on the proposed amendments to Criminal Procedure Code.

Regarding the deputation of Mr. Newport to Australia for the lection of ladybirds, the Honorary Secretary informed the meet- that the gentleman had proceeded to his destination with letters recommendation from Government, which had the effect of keeping wn expenses. The funds, it was said, that had been advanced to on starting were quite sufficient and would hold out till his return India with a consignment, which it was expected would be at the d of the current month. An enquiry elicited the information that . Newport was on leave from his employers without pay, and ring the time he was engaged collecting ladybirds in Australia uld receive £25 from the ladybird fund. In this connection, . Edmiston asked if any member was able to give the results his observations on the action of ladybirds, remarking that his own tea, on which black bug appeared and disappeared, the ybird was present simultaneously. He thought every member ould state just what he observed. The Chairman remarked that his estate on the Pulneys, the ladybirds in crowds appeared with bug. They were of a shining black, and branches with bug and ybirds were exhibited at Bangalore to members of the U.P.A. . Edmiston said his ladybirds were yellow. Mr. Oakes' ladybirds Seegnor were black with red spots. Mr. Gray noticed a strange ect in his direction, half way down the ghaut, which did not fly.

The last subject that was considered by this meeting was the appearance of letters in the Nilgiri Post Offices. Several letters porting loss were read, of which the most important was one from Kodanad Estate, which complained of the disappearance of a eque as well as of a letter. From enquiries instituted, it was ablished that there was no failure to post the letters that did not ch their destination, so that the Post Office was clearly solely ponsible. The Association passed a Resolution to address the stmaster-General, requesting that special enquiry should be made garding these losses, on the proposal of Mr. Gray, seconded by the norary Secretary.

With a vote of thanks to the Chairman, the meeting concluded.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co's Weekly Coffee Report (April 29, 1898) says:—Heavy supplies have again been brought forward in Public Sales and the good demand still continuing the market remains very steady.

Nearly 8,800 bags East India were catalogued which attracted keen competition, desirable Home Trade marks realising extreme rates, whilst the common and medium qualities sold at fully last week's rates.

Large quantities of Costa Rica were offered and nearly all disposed of at firm prices, whilst fine colory parcels show an advance of 1/- to 2/-.

The terme market has been firm this week on reduced Brazilian stocks and dearer cost and freight offers, and quotation mark a rise of 1/- to 1/6 since our last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for the Week ending April 27th, 1898, says:—Bank rate 4%. Bombay Exchange closes at 1s 4d. Brazil Exchange 5 1/16d. Rupee paper 3½% 61⅞. Silver 26⅛d per oz.

Supplies of all kinds which continue to be freely catalogued have again met with a good demand, full prices being paid for all the better kinds, and there being more competition for ordinary and common at steady prices. Fine East India realized extreme values.

Brazil markets are about steady.

Daily receipts averaged 6,600 bags in Rio and 8,500 bags in Santos.

Futures have continued quiet but steady, and close 3d to 9d per cwt. dearer, viz.:—Good average Santos in Havre, May delivery, fcs. 35.75, in Hamburg pf. 29, and No. 7 low ordinary Rio in New York $6.05.

To-day's London official quotations are:—

	May	July	Sept.	Dec., '98.	Mar., '99.

TEA.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, dated April 29th, 1898, says:—

QUANTITY BROUGHT TO AUCTION IN LONDON
FROM 1ST JUNE TO DATE.

	Indian.	Ceylon.	Java.
1897-1898...	1,502,327 packages.	1,083,576 packages.	40,715 packages.
1896-1897...	1,478,453 ,,	1,007,271 ,,	41,232 ,,

31,568 *pkgs.* INDIAN
35,442 „ CEYLON
1,975 „ JAVA
} Total 68,985 packages were offered in public auction this week.

Duty payments during ten months of the season show only a moderate increase owing to the heavy falling off which took place a few months ago; this happily appears now to be giving place to better deliveries. There is now only very little China Tea left for displacement.

Quantity of tea (in lbs.) on which duty was paid at all Bonded Warehouses in the Kingdom from 1st June to 31st March.

	1897-8.	pctgs.	1896-7.	pctgs.	1895-6.	pctgs.	1894-5.	pctgs.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, Eight Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including postage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for line advertisements will be: 4 as. per line for the first, 3 as. for the second, and 2 as. for the third and succeeding insertions. Five-line advertisements from Subscribers will be inserted for three issues for one rupee; non-Subscribers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic occurrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," 11/12, Second Line Beach, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 11 and 12, Second Line Beach, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 3rd June, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nilgiris.

COONOOR, 26*th May*.—*Weather.*—Still very showery weather with occasional thunder-storm 2·20 inches this week. *Crops.*—Coffee in excellent heart, tea also flushing very well again at last. *Health.*—Health very indifferent. *Labour.*—Labour ample, though coffee coolies have mostly been paid off and have returned to their villages.

KULLAKAMBY, 25*th May*.—*Weather.*—Heavy rain and some hail has fallen during the week, and the weather continues cloudy. Work nearly over in most estates. *General Health.*—Fever still very common, and some estates have nearly half the labourers laid up.

S.-E. Wynaad.

DEVALA, 25*th May*.—*Weather.*—Since my last report the weather was very trying, and from the 18th instant every evening we are having good showers of rain followed by thunder and lightning.—*Crop.*—The spikes have set, and the crop seems everywhere a bumper; tea flushing well. *Grain.*—Rice 8 and 9, salt 8, ragi 16, cholum 16 measures per rupee. *Health.*—Fever, diarrhœa and dysentery are still prevalent.

IMPORTANT INSECTICIDES.
II.

The following are further extracts from the publication referred to in our last issue :—

PURE KEROSENE.

Kerosene, or coal oil, is occasionally used directly against insects, although its importance as an insecticide is in the combinations with soap and milk described below. Under exceptional conditions it may be sprayed directly on living plants, and it has been so used, even in the growing season, without injury. It is apt, however, even in the dormant season, on leafless plants, to do serious injury or to kill the plant outright. The pure oil should only be applied as a winter wash to the older parts of plants, either in a spray or with a sponge, using the least possible quantity. Its use is not advised, save in exceptionally bad cases of infestation, and during the dormant period, and should never be attempted after the first sign of spring growth appears. Kerosene is now being used to a certain extent, also, mechanically combined with water in the act of spraying, and is less harmful in this way than when used pure, as it is broken up more finely and is better distributed; but the danger to tender plants is not altogether avoided by this means. Many insects which cannot be destroyed by ordinary insecticides, or where it is unsafe to spray the plants themselves, may be killed by jarring them from the plants into pans of water on which a little kerosene is floating, or they may be shaken from the plants on to cloth-screens saturated with kerosene, the crude product being preferable for the latter purpose. As a remedy for the mosquito, kerosene has proved very effective. It is employed to destroy the larvæ of the mosquitoes in their favourite breeding-places in small pools, still ponds, or stagnant water; and where such bodies of water are not sources of drinking-supply or of value for their fish, especially in the case of temporary pools from rains, which frequently breed very disagreeable local swarms, the use of oil is strongly recommended. The kerosene is applied at the rate of 1 ounce to 15 square feet of water surface. It forms a uniform film over the surface, and destroys all forms of aquatic insect life, including the larvæ of the mosquito, and also the adult females coming to the water to deposit their eggs. The application retains its efficiency for several weeks, even with the occurrence of heavy rains.

THE KEROSENE WASHES.

The Kerosene and Soap Emulsion Formula.

Kerosene	gallons 2
Whale soap (or 1 quart soft soap)	pound ½
Water	gallon 1

The soap, first finely divided, is dissolved in the water by boiling and immediately added boiling hot, away from the fire, to the kerosene. The whole mixture is then agitated violently while hot by being pumped back upon itself with a force pump and direct discharge nozzle throwing a strong stream, preferably one-eighth inch in diameter. After from three to five minutes' pumping the emulsion should be perfect, and the mixture will have increased from one-third to one-half in bulk and assumed the consistency of cream. Well made, the emulsion will keep indefinitely, and should be diluted only as wanted. For use for the treatment of large orchards, or in municipal work requiring larger quantities of the emulsion, it will be advisable to manufacture it with the aid of a steam or gasaline engine, as has been very successfully and economically done in several instances, all the work of heating, churning, etc., being accomplished by this means. The use of whale oil soap, especially if the emulsion is to be kept for any length of time, is strongly recommended, not only because the soap possesses considerable insecticide value itself, but because the emulsion ma with it is more permanent, and does not lose its creamy consisten and is always easily diluted, whereas with most of the otl common soaps the mixture becomes cheesy after a few days a needs reheating to mix with water. Soft soap answers very w and one quart of it may be taken in lieu of the hard soaps.

In limestone regions, or where the water is very hard, some of t soap will combine with the lime or magnesia in the water, and m or less of the oil will be freed, especially when the emulsion diluted. Before use, such water should be broken with lye, or ra water employed; but better than either, follow the milk emuls formula, with which the character of the water, whether hard soft, does not affect the result.

The Kerosene and Milk Emulsion Formula.

Kerosene	gallons 2
Milk (sour)	gallon 1

Heating is unnecessary in making the milk emulsion, wh otherwise is churned as in the former case. The change fron watery liquid to a thick buttery consistency, much thicker th with the soap, takes place very suddenly after three to five minut agitation. With sweet milk difficulty will frequently be experienc and if the emulsion does not result in five minutes, the addition o little vinegar will induce prompt action. It is better to prepare t milk emulsion from time to time for immediate use, unless it can stored in quantity in air-tight jars, otherwise it will ferment a spoil after a week or two.

How to use the emulsions.—During the growing period of summ for most plant-lice and other soft-bodied insects, dilute the emuls with from 15 to 20 parts of water; for the red spider and otl plant mites the same, with the addition of one ounce of flowers sulphur to the gallon, for scale insects; the larger plant bu larvæ, and beetles, dilute with from 7 to 9 parts water, apply w spray pump.

For winter applications to the trunks and larger limbs of trees the dormant and leafless condition, to destroy scale insects strong mixtures may be used even to the pure emulsion, which latter ca not be sprayed successfully, but may be applied with brush sponge. Diluted with one or more parts of water it may be appl in spray without difficulty. The use of the pure emulsion is her treatment, and only advisable in cases of excessive infestation, and general it is much better and safer to defer the treatment until t young scales hatch in the spring, when the nine times diluted wa may be used with more certain results and without danger to plan The winter treatment should be followed by a use of the spri wash to destroy any young which may come from female sca escaping the stronger mixture.

Caution.—In the use of kerosene washes, and, in fact, of all c washes on plants, the application should be just sufficient to w the plant, without allowing the liquid to run down the trunk a collect about the corum. Usually at this situation there is a cav formed by the swaying of the plants in the wind, and accumulati of the insecticide at this point, unless precautions be taken, m result in the death or injury of the plant. It is advisable to mou up the trees before spraying and firmly pack the earth about t bases whenever it is necessary to drench them thoroughly, a care should be taken in refilling the tank that no free oil is allow to accumulate gradually in the residue left at the bottom.

TIME TO SPRAY FOR SUCKING INSECTS.

For the larger plant-bugs and theophides, or active plant-l and all other sucking insects which are present on the plants inju ously for comparatively brief periods, or at most during summer or

treatment should be immediate, and if in the form of spray on plants, at a strength which will not injure growing vegetation. scale insects and some others, as the pear psylla, which hiber- e on the plants, two or more strengths are advised with most of liquid insecticides recommended, the weaker for summer appli- ions and the more concentrated as winter washes. The summer shes for scale insects are most effective against the young, and atment should begin with the first appearance of the larvæ of the ing, or any of the later broods, and should be followed at intervals even days with two or three additional applications. The first od, for the majority of species in temperate regions, will appear ing the first three weeks in May. Examination from time to e with a hand lens will enable one to determine when the young ny brood appear; the winter washes may be used whenever sum- r treatment cannot be successfully carried out, and are particularly antageous in the case of deciduous plants with dense foliage ch renders a thorough wetting difficult in summer, or with scale ects which are so irregular in the time of disclosing their young t many summer treatments would be necessary to secure any- ere near complete extermination. In the winter also, with de- uous trees, very much less liquid is required, and the spraying y be much more expeditiously and thoroughly done. In the case badly-infested trees, a vigoeous pruning is advisable as a pre- inary to treatment. As winter washes for temperate regions, the osene mixtures and whale oil soap solutions, particularly the er, have so far given the best results. These stronger mixtures y be applied at any time during the dormant period of vegetation, d, with deciduous trees, preferably immediately after the falling of foliage in the growing season, any of these stronger washes would se the loss of foliage and fruit, and the more concentrated proba- the death of the plant.

NOTES.

e transport of fruit. In another column we print an interesting article on a new method packing fruit for export. In connection with the length time that fruit will bear transportation, it is worthy of te that the Jamaican Agricultural Society lately received ox of Californian oranges which were in excellent condi- n thirty days after being packed.

other coffee district? There is not much more to fear from the Transvaal than from eensland for the next many years, in the way of affecting e coffee market, though our friend the *Produce World* inks otherwise. It says:—

"Transvaal coffee will probably shortly become a competitor in the rkets. According to the report of the Pretoria Agricultural ciety and Transvaal Agricultural Union, all the eastern Transvaal m Spelonken in the north to Vryhead in the south contains cts of land suitable to coffee, and some farmers, besides growing their own consumption, find the berry pays better than sheep- ming."

planting con- cession. We understand that a valuable concession of about ten thousand acres of forest land has been definitely obtained m a petty Rajah by Mr. E. C. Vernède, a well-known Nilgiri nter, now resident at Coimbatore. The land is suitable for ffee, both Arabica and Liberian, tea, cardamoms, pepper and on. It is easily get-at-able from both Coimbatore and Palghat. The labour supply is ample, both Coimbatore Tamils and Malayalees, villages of the latter being only some 15 miles off the concession. For the first six years the land is free of assessment, and from the seventh a rupee an acre will be charged all round. We believe Mr. Vernède is entertaining applications for the disposal of a portion of his valuable concession.

The cocoanut market. The market for the products of this valuable tree has begun to improve again, mainly from the greatly increased demand for copra (the dried kernel) from Russia. The London price is usually dependent on the price of cocoanut oil, but the Russian demand has resulted in a very marked divorce between the relative value of the oil and its raw material. Direct shipments from Ceylon are said to account a good deal for the increased Russian demand. It is a fact not generally known in India that many of the most prosperous Tea Companies of Ceylon have invested a large proportion of their reserve capital in cocoanut plantations, which have for many years been regarded as the Consols of tropical agriculture.

To mend China. To planters, above all mofussil residents, well-tried recipes for mending articles of household use and furniture, should be of great interest. The following one is taken from the pages of the *Indian Cabinet Maker*, a Calcutta Trade journal:—

"One of the least known, though also one of the simplest and most effective of cements for this purpose, is white oil-colour such as is usually sold in tubes, from which it is squeezed out in the desired quantity. Broken things should always be mended as soon as possible after the accident, but, of course, there are occasions when this is not feasible. In such a case, without any previous preparations of any kind, merely paint the broken parts with oil, press them into position, tie them in position, or otherwise secure them, if possible, and the operation is complete. The only precaution to observe to ensure perfect success is to put the mended article away to dry thoroughly for six weeks; after that period, however, neither heat, nor cold, nor moisture should affect the cement. If, after complete drying, any colour remains, having possibly oozed out, it must be carefully scraped off with a knife before the article is taken into use again, and after it has dried. (2) If any kind of earthenware vessel is cracked and leaks, it can be so treated as to be quite of use again. Put the cracked jug, or whatever it may be, into a fish kettle, or other suitable vessel that will hold it conveniently, covering it completely with cold milk. Set it over a moderate fire, let the milk boil up gradually, and as gradually nearly boil itself away. When the liquor has been absorbed by one-half, stand the vessel aside, and when the contents are quite cold, the jug or dish will hold water again."

America's drink bill. The following is a comparative statement of the cost to the consumer of stimulating drinks, bringing together into one group alcoholic and non-alcoholic stimulants, which, at retail cost, were consumed to the value of 1,055,418,137 dollars:—

	Dollars.
Alcoholic drinks	901,218,011
Non-alcoholic stimulants—	
Coffee	121,726,002
Tea	29,474,124
Cocoa	3,000,000
Total...	1,055,418,137
Total, 1896...	1,016,126,400

The above represents a yearly *per capita* expenditure for beverages of 14,50 dollars for the 72,807,000 inhabitants of the United States, or about 4 cents per day. The above figures seem to show that the cheaper and the milder stimulants are growing in favour, and are steadily reducing the use of fiery liquors.

The quantities of the four leading beverages consumed for the year ending June 30th, 1897, are estimated as follows :—

	GALLONS.
Coffee	... 1,217,260,020
Beer	... 1,069,310,262
Tea	... 564,537,740
Spirits and wines	... 111,755,140

The green bug on the Pulneys.

I hear, says a Lower Pulneys correspondent, from the Nilgiris that Mr. Nicholson has no bug to feed his lady-birds on when he gets them! I wish I could say the same of the Pulneys! At this time of the year in 1897 the bug had obtained a firm hold of the coffee in very large colonies, and though we are anything but free in this year of grace 1898, this does not bear comparison with last year. On the two largest estates on these hills *liming* has been and is being resorted to. In one case the lime is being applied to the roots of the trees, ½ lb. to a tree; in the other the lime, 1 to 2 lbs. to a tree, was sprinkled over the trees and on the intervening spaces, and the bug wherever visible carefully rubbed off by hand and killed. This no one expects to be anything but a severe check to the bug as soon as it appears; it would be quite a hopeless method when the bug has multiplied to any extent. In spite of this, then, on all estates on the south side of the hills there is bug, and I see that here and there it is getting in its deadly work, and branches are dying back from the tips, and the young unformed berry is dropping off, and where the bug is thickest this is only on the native coffee as yet; the whole tree is showing up decidedly black already. I am glad to say this is distinctly rare this year. On the Northern Estates there is so little bug that nothing is being done to check it in any way. I think this is a mistake, for bug increases wonderfully quickly under favourable conditions, as these estates may find to their cost! Perhaps, however, having spent money on lady-bird importation, the proprietors mean to rely on the lady-bird and nothing else. For all our sakes let us hope that the lady-birds, or other causes, will effectually choke off this awful pest.

Irrigation of tea.

Much has been advanced in favour of the irrigation of coffee to make a certainty of the dreadfully anxious blossom time. Little, however, has been advanced with regard to the use of water on tea gardens in times of drought, which occur regularly over more or less extended periods in every tea district in India at least. Except in exceptional seasons, artificial irrigation would never be able to "save the crops," but it could at least be depended on to add a very considerable percentage to the yield in most years.

It is interesting to see that the *Indian Planters' Gazette* has lately taken up the subject in reference to Assam. Failure of rain there at the critical *post* pruning period retards the flush for a month or more, or else produces a tough leathery leaf that turns out very badly-coloured and cup-weak tea. Early and copious rains, moreover, contro a great extent the ravages of red spider and other pe This is in Assam. On the Nilgiris we have always noti that while the intensity of red spider seems to dep wholly on the length and completeness of the drought, i just the other way about with our principal pest, *i.e.*, fl worm. This pest, which is a particular form of bud-ro we have not noticed described in Dr. Watt's Tea Pests quiescent in the dry season, but showery weather im diately hatches out the young broods. Whether soaking the ground alone would have the same effect we can say, as the life history of the insect is unknown. Be as it may, as yield depends on moisture, it is better to h large flushes with the risk of flush-worm than to h practically no flush at all.

Where hill streams are unavailable, our contempor advocates well-sinking, which on most South Indian gard would scarcely be needed. Irrigation on flat land prese no difficulty except that of efficient subsoil drainage draw off the superfluous water. On hill gardens a syst of waterholes, especially if dug so as to form part o permanent drainage system, would perhaps be necessa On the objections to irrigation we hope to touch in a fut issue.

The London Market.

Coffee.—Arivals continue to pressed forward in very large qu tities, so much so, indeed, that it is impossible to dispose all during the time allowed each day for the auctions. I about 26,000 bags have actually passed the hammer, a as the demand has continued very good, practically whole were sold, and only a very few parcels of undesira sorts were bought in. The bulk have consisted of home trade descriptions, such as Mysore and Costa R and with keen competition the whole have been disposed at prices which mostly show an advance of from 1*s.* to while the small sizes of Mysore have sold at a lar advance than this. Medium Costa Rica between 65*s.* a 85*s.* has also sold very fairly at dearer prices, but the lo qualities, suitable only for export, at first declined from to 3*s.*, but since then there has been some improvement rates are about unchanged. In the terminal market, altho only a small business has been done, prices have harde about 1*s.* to 1*s.* 6*d.* per cwt.

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain ton :—

61·50	lbs. Nitrogen.
57·38	„ Potash.
14·92	„ Lime.
13·68	„ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the 1898-1899 crop of seed f the parent trees of above analysis at Rs.6 per pound contai about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere from the

Indian Teas.—The market opened with an active feeling, d for the larger quantity brought forward on Monday ces showed a general advance. Common qualities, which med a considerable proportion of the supply, rose ½*d.* th brisk bidding at the improvement. The upward move- ent in prices for these kinds is no doubt due, in a great easure, to speculative buying, as there certainly does not pear to be any justification for so sudden an advance, nsidering the large proportion of these grades to the total ock and the considerable shipments of similar tea from lombo. For the next higher descriptions the rise is even ore pronounced, and may only prove temporary; at the me time, there are stronger reasons for the advance in ese sorts than in the common kinds. It is, therefore, obable that prices for these may not fall to the level previ- sly ruling, as the supply for some time to come is not kely to be more than the trade can conveniently absorb. he finer kinds have sold readily at firm to advanced rates, d the market will in all probability continue very strong ing to the gradually declining quantity available, which nnot be augmented until the arrival of the new crop some onths later on. At the public sales 31,568 packages were ought forward and only about 1,700 withdrawn, and for xt week a fairly liberal supply is catalogued.

LETTERS TO THE EDITOR.

IRON FACTORY ROOFS.

SIR,—Can you, or any of your readers, kindly answer the llowing queries:—

(1) A cheap and efficient method of covering a corrugated on roof, so as to prevent extremes of temperature? The vering must be light enough to use the roof without additional ams or rafters.

(2) The best method to secure an iron roof, so as to obviate l risks of its being carried away by wind? Would stout wire enough, running transversely from eave to eave over ridge, ssing through wall a foot or two below eave and then attached rafter? I have already wall-plate bolts built in the walls. The ires would hold the iron sheets on to the rafters. To hold e rafters and wall-plate bolts, I could attach stout wire ropes om the "couplers" to inside flooring beams, if required.

I wish, Mr. Editor, you could arrange for a special staff of rrespondents to answer these sort of queries.

Yours in doubt,

A SUBSCRIBER.

PLANTAINS FOR EXPORT.

SIR,—I see the question of the cultivation of plantains for export discussed in your paper. It would be interesting to myself and, no doubt, many other brother planters to get some useful hints and information on the subject, through the medium of your valuable paper, from some one who can speak from experience. Provided the fruit could be conveyed quickly enough to the nearest port, there seems no reason why we should not be able to export it profitably, as it grows freely and almost anywhere. Answers to the following questions would be interesting:—

(1) The best variety or varieties for exporting.
(2) Where such can be obtained?
(3) How to pack for export? Should the bunches be sent whole or sub-divided?
(4) How to judge when to cut the fruit so as to arrive at destination in good condition?
(5) Which is the best market for them?
(6) How long will the fruit keep after cutting?
(7) How to cultivate the trees to best advantage?
(8) Any other points of interest not covered by foregoing questions.

MERCARA, COORG, 13*th May*, 1898. } ED. FENNELL.

A CHEAP AND GOOD BUNGALOW ROOF.

SIR,—These are the *four requirements for a good roof:* 1st, to be watertight; 2nd, fireproof; 3rd, sound proof; and the 4th follows, thick enough to keep out heat or cold. Besides which, a roof ought to look pretty. I made an open roof with a good pitch to it, which always gave a pretty exterior and interior appearance to "cottage-building." The "couples" had their corners bevelled, and were wood-oiled, set two feet apart; on these were nailed strong reepers set across 21 inches apart, pretty strong, $3'' \times 1\frac{1}{2}''$. On ridge were placed *rider couples* carrying ridging giving a 3″ bottom ventilation when covered with continuous roofing. At end of reeper at "eaves" was nailed a strong oiled batten $3'' \times 3''$, after which continuous roofing was placed across, nailed only at top end, to reeper, the upper iron roofing overlapped it $2\frac{1}{2}$ inches, till it was covered 9 inches under "rider" couples on ridge; then rider couples were covered with iron with a $2'' \times 2''$ batten to prevent tiles or bricks from slipping. On the iron was placed a double layer of matting, over which tiles $10'' \times 8''$ and 2″ thick, or failing these, brick, all placed horizontally and "bonded." Finally, a pretty board ridging finished the roof; also side and bottom had boarding ornamented. About chimneys, an iron lap of lead sheeting protected part from rain when chimney penetrated roof, so the lead lapped over the continuous roofing. A prettier, cheaper, and more effective roof I ask the next man to suggest. All was made on the estate.

CALCUTTA, 13*th May*, 1898. } VALE.

TEA ON THE NILGIRIS.

SIR,—In the last number of your papers there is a report of the Annual General Meeting of the Nilgiri Planters' Association. Among them I notice some interesting remarks by Mr. Windle, the Honorary Secretary, on the subject of improving the quality of our teas. He attributes, among other causes, the poor figure too often cut by Nilgiri teas in the London market to deficiency in withering accommodation. In this he is undoubtedly right. But he does not go far enough. The haziest

notions are often held as to what "withering" means. Until such ignorance is cured, the best-equipped of factories will not improve matters. There are, perhaps, three tea gardens on the hills which are well up-to-date in the modern methods of tea-manufacture. These command good competition in the Lane, and their prices are usually good; sometimes very good, indeed. The moral is obvious.

The question of making good tea is a problem that cannot be solved in the tea-house alone, however excellent the factory or the tea-maker. The Nilgiris, as a district, are as backward in their system of pruning, picking and cultivation, generally, as they are antiquated in their factory appliances. That is to say, they are about a quarter of a century behind the times.

The climate is fair enough, the soil fair to indifferent, the jât very bad (50°/₀) to very good (3°/₀), while, though it may sound offensive, the men (as tea planters) about on a par with their factories.

More power to Mr. Windle, says

A Nilgiri Tea Planter.

GENERAL ARTICLES.

TEA PESTS AND BLIGHTS.

(*Continued from page* 236.)

Plucking. On the character of the pruning given to the bush, discussed in our previous issue, depends almost altogether the flushing powers of the bush. We might also add the style of plucking. The principles of vegetable physiology involved in the action of flushing is little noted by the ordinary planter. The aim of every plant being to reproduce its kind, *i.e.*, to seed, the act of flushing is simply an endeavour or, rather, repeated endeavours to form wood that will ripen sufficiently to bear seed. This tendency to ripe wood the planter does his utmost to check by continual plucking, which must inevitably result in a great strain on the tree.

Leaving Dr. Watt for a moment, it is obvious that the course of the planter must be a happy choice between the two extremes of too light and too severe plucking. The former, by allowing the wood to ripen, will stop flush and allow a profuse blossoming to take place. The latter, by too great a check to the plant, will likewise stop flushing (turning *banjhi*) and moreover seriously injure the bush.

Dr. Watt has interesting views on the *banjhi* question. He looks upon it, not, as do so many, as a cause, but as a result. Ill-health from various reasons is the inevitable cause of barren or *banjhi* buds. The usual idea is that a *banjhi* bud acts as a sort of dam to the free flow of sap, and that plucking the banjhi leaves will cause the sap to burst out elsewhere in healthy flush. To a limited extent the practice is good, as it follows of course the general principles of plucking in general. But as the formation of *banjhi* buds is the last effort of the plant to regain some of the strength lost in giving continual crops, the plucking of these buds can only act as a very alleviative, and must gravely accentuate the ill-condition of the tree. The cure of *banjhi* buds does not lie in plucking them; better cultivation, more efficient drainage, manure, all these will do a great deal to restoring the normal health of the bush.

Different styles of plucking vary greatly in their effe on the bush. It may seem strange, but it is an undoubt fact that fine plucking, *i.e.*, picking for quality, is a greater strain on the bush than plucking coarsely or quantity. The scientific explanation is simple enough. the latter style, it is usual to allow a good growth bef plucking the three leaves and bud. In quality pluckin the leaf (two leaves and a bud) is picked at a young stage, and consequently both the remainder of the shoot a the remaining leaves are far less mature than in the form case. The interval between the two styles also diff naturally, quality plucking being "little and often" agai the "much but seldom" of quantity picking.

A combination between these two styles is the int mediate one of two leaves and-a-half and the bud. T practice has, however, almost nothing to recommend it, a in effect combines the vices of both, with the exception avoiding the extra length of stalk. The great fault this method is that, while the growth of the flush bef plucking is the same as in quality plucking, *i.e.*, three lea (excluding the *jarium*) and a bud, only half, or oftene quarter of a leaf, is left to sustain the vital processes of plant. It were far more rational to allow a growth of extra leaf, *i.e.*, four and a bud, and to boldly pluck th leaves and a bud at once.

We have perhaps outrun the order of our subject rushing at once from pruning to what we may call "curr plucking." On the initial plucking or tipping after prun is of course the most important of all, and differs accord to the style of plucking intended. For quantity plucki seven leaves and a bud are allowed to grow, while quality, only five and a bud are allowed to grow, three an bud and two and a bud being the respective pluckings. severer the prune, of course, the greater length of shoot be left before plucking.

THE WAR AGAINST BLIGHTS.

Take any blight you like to mention, let it be disease, red spider, brown-rust, flush-worm, or black b Each must have a life history of its own, and just w that history is, is the most important thing you can possi find out. It isn't easy, granted. If you can't trace e link, you can at least direct your efforts at certain sta of its existence. You have a certain pest on your tr suppose it is bug and that it is in full vigour. It i sucking not a biting insect. Well, as you can't poison food very well, you can try to choke it by spraying a vis wash—kerosine emulsion—over it, or else you can us caustic-like lime to burn them out, or choke them poisoning the air with noxious gases. Well, we'll supp you've done your best, spent a good deal of money partially got rid of the pest. In a short time you will that the pest on neighbouring untreated parts has likew disappeared, or partially so. Its eggs, or its pupæ, o few old comatose insects, must be in existence somewh to carry on the breed next season. Now where are th eggs or pupæ? There aren't many alternatives op Either they are resting in neighbouring jungle, or, whic far more likely, concealed either on the leaves or branch or in the soil itself. A few trees should be selected

ervation, and isolated by means of fine gauze wire if sible. To test the leaf theory, wash every leaf and ng shoot of the tree in kerosine emulsion. In another wash the stem and old branches only. In a third, t the collar and the roots as far as possible in a similar nner. With a fourth tree, pick up all dead leaves twigs only, and burn them. While the fifth and last— soil test—would be best carried out by removing all the face soil to a depth of, say, a foot, replacing it by burnt thoroughly mixed with a small quantity of artificial nures. Such experiments should, if possible, be dupli- ed. The cost of the gauze wire will not be slight, it is e, but should not be exactly ruinous. If, however, the ze wire is not obtainable, somewhat more extensive eriments must be carried out in the field. Whole rows trees, instead of individual specimens only, should be ated. If all these methods prove inconclusive the first r, try again and again.

The great thing is to spend all the money allowed to bat the pest *before* it makes its appearance in its full nbers. If you can once stop the first broods, success is rs.

Almost every pest or blight can be attacked in the same y, and with undoubted success if perseverance and care freely given to the object.

But it must be remembered that our most dangerous ghts can only exist on sufferance, as it were. The trees st be unhealthy from other causes, such as injudicious ning, cultivation, or manuring before a pest can effect ure lodgment. The presence, therefore, of a pest is a n patent that all is not well with the tree. The true ses must be searched for and found. At first sight it l prove a most puzzling tangle to unravel. But a little e and accurate observation will soon lead one on the ht track. We will take for example any pest which ms prevalent all through the district. As it seems thrive in all sorts of places and under all sorts of con- ions, the task is no easy one to find out which conditions y be called causes, which can be termed effects, and se which are only accidental. Let the observer begin his own estate. The pest can be found all over the ate. Some of the worst patches are, however, on fields of parently distinctly different soil and aspect. He must down all the points he can of *resemblance*, such as shade, nner of soil working, drainage, manuring and so on. ints of difference need not be noted at all. The fewer points of resemblance the easier will be his subsequent rk. For he can with justice take for granted that some least of those conditions identical in both cases—if his list correct—tend to encourage the pest. The next thing to is to turn his attention to the fields which are most free m the pest. If he can trace all the points of resemblance being present in the unaffected field, he had better race his steps and do the work again. We will suppose t at last two or three of the supposed disease-inducing ditions are absent in the healthy field. He cannot go ch further in the work on his own estate. He must now it neighbouring gardens and test his theory. By degrees d by frequently retracing his steps, he will have at last nd out a group or combination of causes almost invari- ly present in the most diseased fields and present in only slight degree in healthy plots. These causes may not have any surface connection with each other, and it may be that singly they are not of the slightest effect on the disease, but that if found in a particular combination, disease is almost always present. He must now trace the points of resemblance in the exceptions to his rule. From here the way is easy, and all he has to do now is first perhaps to correct his theory by a similar investigation into the causes that make for health, and to finally test his conclusions by removing the conditions that seem to so strongly favour disease.

PRESERVING FRUIT FOR EXPORT.

A New Process.

The following from the *Australasian* will be read with interest by all interested in the possibilities of the cultivation of fruit for the English market :—

"At a recent meeting of the Fruit Growers' Association, Mr. W Sutherland exhibited samples of the following fruit by his process. —Peaches: Hale's Early for 10 weeks; Early Crawford, 9 weeks; Royal George and another variety, 6 weeks. Pears: William Bon Chretien, 9 weeks; Doyenne Boussoch, 6 weeks. Plums: Early Green Gage, 10 weeks; Washington (soft and discoloured), 10 weeks; Orleans, 8 weeks; Blue Belgian, 8 weeks; Japanese and yellow plum, 8 weeks; Nectarines, 10 weeks; Tomatoes, 5½ weeks. Grapes: Black Prince, Muscat, Gordo Blanco and Lisbon, all for 6 weeks. Apples (early): Duchess of Oldenburg, 10 weeks; William's favourite, 10 weeks, and Emperor Alexandra, 9 weeks. All these samples were kept at the cold store of Mr. Ridge, in Fitzroy.

"This process is founded on two principles: first, that all fruits last in better condition for a longer time the cooler they are kept, provided that the temperature is not taken below the freezing point of water; and second, that the surface of the fruit must be kept dry. The necessity of keeping the skin of fruit dry arises from the fact that the spores of yeasts, moulds and fungi generally, which lie by the thousand on the skin of fruit, are unable to germinate successfully without a supply of water, although a film of water quite invisible to the eye, or imperceptible to the touch, amply suffices for their modest requirements. Some fruits are so strong in the skin that even if their surface is moist enough to allow the spores to germinate, the young fungi are unable to break through the skin to get nourishment for further growth, and so their inroad is arrested. But in the long run moisture is bad for even the hardiest of fruits. Thus fruit must be kept dry to avoid the attack of fungoid diseases. But in addition to this danger from without, fruit is exposed to danger from within, because chemical changes are going on within its substance, producing all the remarkable effects of ripening, but not stopping there, for ripeness passes rapidly into over-ripeness. The higher the temperature the more rapid the chemical changes, and this is the reason given why fruit must be cooled if it is to be kept for a long time at its best. But the use of cold is claimed by Mr. Sutherland to confer another great advantage, inasmuch as growth of yeasts, moulds and fungi generally is greatly slowed down at low temperatures, and hence on the surface of cold fruit any spores that do germinate in favoured positions for working mischief grow so very slowly that after weeks they are still too small to be visible to the naked eye; whereas during the same time on warm fruit they would have converted it to a mass of corruption. The author of this process, therefore, regards dryness and coolness as the two main points in the keeping of fresh fruit. There is some difficulty found in providing the two necessary conditions at the same time, for everyone is familiar with the tendency of a cold surface to precipitate moisture from the atmosphere in the form of water, as, for instance, in the deposition of dew. On this account cold fruit is especially troublesome to keep dry. In the Perkins' process the difficulty was overcome by circulating amongst the fruit cold air, so dry that the fruit could not deposit any moisture out of it. But this necessitated a special sort of refrigerating machine for fruit, as it is rather hard to make cold air dry enough for the purpose. Moreover, another difficulty is that the driving of air for weeks over fruit must rob it of perfume and tend to shrivel it a little by carrying off moisture.

"In the Sutherland process the fruit is kept dry by wrapping it in the usual way in dry paper, which is kept from being spoiled by the moisture in the atmosphere by enclosing the fruit (so wrapped) in wax-paper bags, which are sealed up hermetically or nearly hermetically. These bags may be of any size, from that large enough to line a whole case down to that so small as to contain only a single fruit. When the bag or bags are sealed up, and the lid of the case nailed down, you have the fruit insulated from external action in lots varying with the size of the bag used. The case can then be refrigerated by any appliance in use for the purpose; there is no necessity to employ only refrigerating machines of special construction for supplying dry air. The refrigerating chamber may be dripping with water without harming the insulated fruit, although, of course, it is not advisable to let the case get wet unnecessarily. The whole case is cooled as quickly as possible nearly to 32 degrees Fahr., and is to be kept at about that temperature. Any moisture that the fruit gives off is absorbed by the paper, and in this way the fruit is kept both dry and cold with ordinary appliances.

"In addition to complying with the two essential conditions for keeping fruit sound for a long time, the following subsidiary advantages are claimed for the process: First, if a bad fruit is by accident packed in a case, the insulation confines its evil effects to the bag in which it is enclosed; second, the insulation prevents the loss of perfume and moisture, so that the fruit has the best chance of maintaining its fresh appearance, flavour and perfume; third, the insulation still protects the fruit from moisture when for distribution it is taken from the cold store and exposed to the comparatively warm and moist ordinary atmosphere, the retailer keeping the fruit for a day or two till it ceases to be cold, when it can be safely exposed to the air. Its cheapness and simplicity are obvious, the process having been specially simplified down to make it applicable on the smallest orchard. It saves its own cost by reducing freight, because it enables the cases to be packed solid in the ship, thus saving the space at present wasted in ventilation. All that the orchardist has to do is to place the fruit in bags, or in the case lined with a single large bag, and to seal up the mouth of each bag by running a warm iron along it. He is, of course, expected to excercise his experience and judgment in determining the stage at which each fruit will be packed. For example, apricots and peaches must be full grown, but without soft spots; grapes ripe but free from over-ripe berries; pears full grown, but still green; apples may be allowed to get riper than they usually are for export; plums should be taken just before softening begins, and so on. It is essential to the successful exportation of Australian fruit that it should be cooled almost to the freezing point of water, in cool chambers on land before shipment, and that the shipping companies should be expected only to keep it cold, and not to do any of the cooling, for which the arrangements on board ship are absolutely unsuitable. Mr. Sutherland is emphatic in asserting that blunders will be the order of the day until the preservative effect of cold is taken advantage of for fruit in the same manner as for butter, meat and eggs. It is not a matter of barely getting the fruit home in saleable condition, but so that it has weeks of vitality in it, so that distributors can handle it without risk, for which the producer always has to pay. For a large trade the retailer's risk must be reduced to a minimum; and for the exporter there is this blessing, that in reducing the English retailer's risks, he is reducing his own still more."

CORRESPONDENCE RE RUBBER.

THE following correspondence will interest those in India who have gone in for rubber:—

Resident-General's Office, Selangor, Malay Peninsula, Kuala Lumpur, 15th December, 1897.

To the Secretary, Planters' Association, Selangor.

SIR,—I am directed to enclose copy of a preliminary report by the Superintendent of Government Plantations, Perak, on the tapping of the Government Para rubber trees at Kuala Kangsar, which the Resident-General thinks may possibly be of interest to the m of the Planters' Association.—I have, &c., A. BUTLER, *Secre the Resident-General, F. M. S.*

Government Plantations Office, Taiping, November 24th, 1

To the Secretary to Government, Perak.

SIR,—In reply to S. G. $\frac{6464}{97}$, I have the honour to forw following report on the work done in connection with Para trees at Kuala Kangsar.

2. Some months ago the Director of Kew wrote to me. I heard from Sir Hugh Low that the Kuala Kangsar trees exude when tapped, and asked, with a view to information, reason.

3. It will be seen from this report that the work for the not yet completed, and I would particularly point out th experiments have not been conducted to test how much ea will yield, for the reason that these trees are of much greate to the Government at the present time as seed-bearers than producers: as an instance of this, I would mention that appl for 70,000 seeds have been received for the current year (of 25,000 have been supplied) and an application filed for 100,00 next year.

4. The Para rubber trees (*Hevea Braziliensis*) at Kuala K were first tapped during the month of August, and the wo been proceeding up to the present time. The frequent we have delayed the work considerably. At the end of Octo trees had been tapped, and 88 of dry marketable rubber pr Most of the trees tapped were six years' old, and from these t average of 10 ozs. of dry rubber has been obtained. A few trees years' old, produced 3 lbs. each, but in no instance were the t exhaustive. Two samples have been sent to Mincing Lane for and valuation.

5. *Tapping.*—The trees were tapped with almost V-shape a few inches apart, with a channel down the centre from th branches to the base. An ordinary pruning knife was used the first cuts, and about a quarter of the outer bark remov being taken not to cut too deeply. So soon as this comme callous—which varies from two to several days—the edges cuts were lightly shaved with a very sharp chisel every day occasional interval until the decided quantity has been exude rubber was collected in locally-made tin boxes 6″×4″×2″, n the base of the tree, with the lid partially opened so as to wet or dirt from falling in. When full, this was allowed to the water pressed out (a pinch of salt appears to expedite the lation) and then kept in smoke for about a week to prevent

6. *Time of tapping.*—Para rubber has a short resting seas most of the leaves fall off. The flowers usually appear fi when the tree is in full foliage tapping can be commenc carried on with different trees—until again deciduous. T cuts can be made at any time of the day, and may be left fo in the event of exceptionally wet weather, but the sub tappings should always be done in the evenings, as the rubb ceases to exude with the influence of the sun.

7. *Planting.*—Most of the trees at Kuala Kangsar are pla wet land, subject to be flooded every year. Some, however, high dry land, but my experiments are not sufficiently com say if there is any difference in the yield of rubber on dry wet land.

8. The tree appears to be the most adaptable of any rubb growing from swampy lands to an elevation of several hund and seems to thrive on any ordinary soil. The material poi cultivation is close planting. I recommend not more than apart.

9. *Remarks.*—I am of opinion that a tree 5—6 years' old is of producing $1\frac{1}{4}$ lbs., and a tree 13 years' old 5 lbs. of rubber injury. The cost of tapping, drying, and preparing, I shou mate, working on a large scale, about 30 cents per lb. The

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

on value for dry rubber is from 3*s.* 6*d.* to 3*s.* 8*d.* (sterling) per lb. ld add shat I shall be able to offer some further remarks when periments are completed, and when I receive an opinion on mples sent home.—I have, etc., R. DERRY, *Superintendent of ment Gardens.*

---

ident-General's Office, Perak, Malay Peninsula, Taiping, 4th ary, 1898.

he Secretary, United Planters' Association, F. M. S., Klang.

—In continuation of my letter, No. 3281-97, of the 15th ultimo, directed by the Acting Resident-General to enclose copy of a of Mr. W. Figg, of the firm of Messrs. W. J. and H. Thompson, ing on the samples of Para rubber obtained from the trees at Kangsar.

I am also to call your attention to the report to Mr. L. Wray, or and State Geologist, Perak, recently published in the *or Government Gasette.*—I have, etc., A. BUTLER, *Secretary to nt-General, F. M. S.*

Mincing Lane, E.C., 19th November, 1897.

R. DERRY.

R SIR,—I have received your samples of Para rubber and beg ort on same as follows:—

1. Matta Grossa in character, fairly clear, imperfectly d, but apparently good, strong rubber.

. 2. Matta Grossa in character, fairly clear, slightly prefer- Value 2*s.* 9*d.* to 3*s.* per lb.

market is very good, and you should ship all you can; try and it a little more and keep the bulk up to the standard you sent As a rule the rubber from the Straits is much inferior to that g from South America, but your samples are quite equal to You seem to have more carefully prepared it; ordinary Straits r, imperfectly collected and prepared, is worth about 1*s.* per lb. an the samples you have sent. I hope to do fairly well for the pepper; the market keeps good.—Yours, etc., W. FIGG, for and H. THOMPSON.

* Prepared with a pinch of salt.

---

tly, we insert a letter from the Director of the Ceylon ical Gardens:—

al Botanic Gardens, Peradeniya, April 14, 1898.

Hon'ble the Colonial Secretary.

—I have the honour to report that during the week ended 2nd last, I visited the plantations of Para India rubber at oda and Yattipowa made in 1890-93 by the Forest Department, so some of the estates near Neboda, on which a considerable t of rubber has been planted.

The plantations belonging to the Forest Department are in ood order, and in a year or two many of the trees will be in ion to allow of experiments in tapping being made on them, uch to be desired.

On Culloden estate near Neboda, which I have examined in detail, thanks to the courtesy of the visiting agent, Mr. Grigson, are about 30,000 or more trees in very fine order. The older were grown from seed or cuttings obtained from Henaratgoda . Of recent years the estate has had much seed of its own, is year their crop is expected to greatly exceed that at the al of Government.

A finer lot of trees than those on this estate and the neigh- g estates it would be difficult to find. The oldest trees are urteen years' old, but rival the trees twenty-one years' old at atgoda. This is partly due to the fact that the Culloden trees re widely separated than those at Henaratgoda, being planted ; tea at distances of about 30 feet, partly to the more favourable d conditions of the Kalutara district.

A few experimental tappings have been made on the older n this estate and have shown very good results, better than those obtained at Henaratgoda, on which the data of profit and loss given in the circular recently issued by this department were based. As at present the demand for seed makes it more profitable to keep the trees for seed; these experiments are not being continued just now.

6. From what I saw of the condition of the trees and the results of these tappings, I am strongly confirmed in my previous opinion that the cultivation of rubber bids fair to prove a profitable industry in Ceylon and a useful adjunct to the larger industry of tea and cocoanut cultivation,—I am, &c.,

JOHN C. WILLIS, *Director.*

CEYLON PROPRIETARY TEA ESTATES.

THE report of the Directors of the Ceylon Proprietary Tea Estates Company, Limited, for the year ended the 31st of December last, submitted at the first annual ordinary general meeting held in London on the 25th ultimo, states that the net amount at credit of profit and loss account, after writing off half of the preliminary expenses, providing for general expenses, income-tax, etc., is £6,277. Debenture interest paid to 30th of September, 1897, less income-tax, amounted to £544; three months' debenture interest to 31st of December, 1897, less income-tax, amounted to £181; preference dividends paid for 1897, less income-tax, amounted to £1,242; *interim* dividend of 2 per cent. on the ordinary shares paid to 30th of October, 1897, amounted to £1,549. It is proposed to pay a final dividend of 3 per cent. on the ordinary shares, making 5 per cent. in all, free of income-tax, which will absorb £2,354, and to carry forward to next year a balance of £410. The Directors regret that, owing to a high rate of exchange, the fall in the price of tea, and the high price of rice consequent on the famine in India, the profits for the first year's working have fallen short of anticipations. The crop of tea from the Company's estates was 868,710lbs.: 89,307lbs. were manufactured for others, and 32,799lbs. from bought leaf; the total output of the factories amounting to 990,816lbs. of tea. The yield of tea was 413lbs. per acre, the gross price realised in London and Ceylon was equivalent to 6·940 per lb. and average rate of exchange was 1s. 3-15/32d. for the year. The following is a summary of the acreages of the Company's properties:—Tea in bearing, 2,100 acres; tea not in bearing, 111 acres; jungle, timber, clearings, scrubs and patena, 847 acres: total, 3,058 acres. A new factory has been built on the Radella estate during the year, and other necessary additions to factories have been undertaken. The estates are reported on as being in good order, and arrangements are made to plant about 100 acres with tea and 30 acres with fuel trees during the current year.—*The Planter.*

PRINTING—All kinds of Estate Weekly and Monthly Report and Account Forms, executed at our KARAPARUMBA PRESS.

MANURES.

Fish Guano. Steamed Bone Meal. Poonacs:—Castor, Mowra, Hoongay. **Saltpetre, Crude and Refined** (Nitrate of Potash.) **Nitrate of Soda. Sulphate of Ammonia. Sulphate of Potash. Muriate of Potash. Superphosphates. Phosphate Powder. Kainits Salts.**

Mixtures can be made in any proportion without extra charge. **Packing** can be done to suit transport by bullocks, etc.

Prices will be furnished on application for delivery either at our Karaparumba Works, Calicut, the Calicut Railway Station, Palghat, Mettapollium, Salem, or at our godowns in Cochin, Tellicherry, Mangalore and other places.

Quotations will be obtained and orders booked for any Manures not kept in stock.

F.r.m.

BRITISH GROWN TEA.

WE quote the following article and letter from the *Financial Times*:—

"Owing to the fall in the price of Indian and Ceylon tea, and the maintenance of the artificial rates of exchange on India, the dividends on last year's workings of tea-planting companies are likely to be on a much smaller scale than those of previous years, except in those cases where there are reserve funds for equalising dividends. From information we have received, we believed the remedy for the present depressed state of the tea market is entirely in the hands of the companies themselves. As combinations are now the order of the day, we do not see why they could not advantageously combine to diminish the output of the lower grades of common tea, which, it seems, do not pay to produce at present low prices. We are told that when the prices of common tea were much higher than they are now, owners of estates in the low-lying districts, both in India and Ceylon, adopted the system of plucking one leaf more than was gathered in the higher districts for the purpose of compensating themselves by quantity for comparative inferiority of quality. It appears that this method of working low estates answered very well as long as prices of the grades obtained from the manufacture of the extra leaf were remunerative; but now the production of these grades has become unprofitable, and it is suggested that all tea companies who own estates on which the coarser plucking is practised should agree to discontinue it for a defined period. We learn that this can be done without the slightest interference with the ordinary working of the estates, and though it may increase the cost of the better grades of the tea produced on these estates, the advance in prices of all qualities which would follow from the decreased supply would more than compensate for the small increase in the cost of production. The fact is, as statistics prove, the production and consumption of British grown tea are so nearly equalised that an increase in consumption, which may naturally be looked for from present low prices, or a decrease in the supply would cause an appreciable reaction in market values. As the first is a slow process, the quickest and most certain way of obtaining the desired improvement would be to discontinue the supply of those grades which are now selling at from 4*d*. to 5*d*. per pound in bond and which consumers do not want. There can be little doubt that if proprietors of estates would agree to leave the fourth leaf on their bushes, such a reduction in the supply of tea would take place as would enhance prices of all qualities to a point that would satisfy them, and at the same time not be high enough to discourage consumption, though it would probably curtail the profits of the big retailers who can well afford it. However practicable and advantageous the plan of adopting temporarily the system of finer plucking may be, it would not do to carry it too far. If that is done it will probably let in again large quantities of Chinese common Congu, the importation of which for the last eighteen months the English Government has been striving to increase by giving it a protection of at least 40 per cent. over British grown tea. The reason why this protection of China and Japan tea did not lead to increased imports last year is because consumers fully recognise the comparative cheapness and better qualities of British machine-made tea, and no longer appreciate the peculiar and distinctive flavour China tea acquires from being manufactured by the clammy hands of Chinese coolies. Still it is very difficult to compete with a highly-protected article, and we therefore warn British tea planters to watch Chinese experts next season and the vagaries of our own Government."

"SIR,—My attention has been called to a leading article, under the above heading in your issue of this date, on the conten which, however, I crave your indulgence to make a few rem

"1. *Profits for Season* 1897.—While you are correct i view that these, owing to high exchange and overhead prices of tea, are likely to be curtailed, it is hardly corre opine that 'dividends will,' all round, 'be on a much sm scale,' to use your own words. Undoubtedly, the dividen those companies which in past favourable seasons have mad provision for 'a rainy day' will have to be reduced, in the larger number of instances, where reasonable p sion of this sort has been made, there is not likely to be diminution in actual dividends, though the profit earned ma less. The three principal Ceylon companies which have so issued their reports—namely, the Ceylon Tea Plantations pany, the Standard Company, and the Eastern Produce pany—certainly show small signs of decadence (despite unfavourable season), and they cannot fail to be most satisfa to their shareholders; while among the leading Indian compa —with a few exceptions (where conditions have been unus unfavourable)—there is not likely to be much cutting down

"2. *Quality* vs. *Quality of Produce*.—While there is no d some truth in what you say as regards managers having their power to control the quality by regulation plucking, is not always practicable, being chiefly questions of labour of climatic conditions ruling at different periods of the produ (flushing) season, which extends over nine months of the y The constant endeavour nowadays, both of managers on the and of the home administrations of most of the leading panies, is to produce the best possible quality of tea. Du the year just closed, however, conditions have been in I especially most abnormal, weather being frequently unfav able and the health of the labour force bad, with heavy de rolls, and this is the chief reason of the coarse quality produ This will probably be entirely reversed next season. Ind there are not wanting those who believed that there is some of an excessive supply during 1898 of fine grade tea w may cause a fall in the price of fine Assams. It should noted, moreover, that there have been even in 1897 m notable exceptions of gardens—where conditions were n favourable—sending very fine tea, notably the Assam Compa Doom Dooma, and Jhanzie in Assam, and the Lebong and o Darjeeling gardens.

"3. *Low-lying Districts*.—You appear to have fallen a l into error in regard to this point. It is true that in Ceylo where the best tea is grown at an elevation of from 1,000 u 4,000 or 5,000 ft.—the produce of the districts lying at sea l is mostly poor, and the same remark applies to the produce the so-called bheels or marshes in Cachar and Sylhet. Bu regards Assam—that is, the whole valley of the Brahmaputr which produces the strongest teas, and also parts of Sylhet, even the Dooars, virtually the whole tea planted area is onl few feet above river level, with no deleterious effect on qual but the reverse.

"4. *Return of Chinese Competition*.—You are quite corr no doubt, in the view that any attempt to unduly raise the p of Indian and Ceylon tea, or to seriously diminish the sup of the less highly-priced grades, might possibly give a renew impetus to the cheap China Congou import. This, howeve believe is less to be feared, so far as home consumption is c cerned, than by reason of its standing in the way of, or ha capping, the export trade to Colonial and foreign countries, which direction, much more than to increase consumption Great Britain itself, the expansion, in consumption, counteractive of over-production of Indian and Ceylon tea mainly to be sought."

"I am, &c.,
GEO. SEATON."

Indian Tea Share Exchange, 120, Bishopsgate Street With E.C., April 16, 1898.—*The Planter*.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co's Weekly Coffee Report (May 6, 1898) says:—
e heavy supplies in Public Sale show no signs of falling off at present, l the market on the whole is well maintained.
About 7,300 bags East India were offered and mostly sold, fine Home ade parcels still attracting keen competition, but medium and common ts, in very small lots, were rather easier.
Large quantities of Costa Rica and other Central American were cata- ued, bold colory grades realised full prices, whilst less desirable kinds l steadily.
Futures have been irregular during the past week, and quotations at close are unchanged for near positions and 1/- lower for distant.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for Week ending May 4th, 1898, says:—Bank rate 4%. Bombay Exchange ses at 1s. $3\frac{3}{32}$d. Brazil Exchange $5\frac{11}{16}$d. Rupee paper $3\frac{1}{2}$% $62\frac{1}{4}$. ver $25\frac{7}{8}$d. per oz.
Our spot market continues very steady, the heavy supplies at auctions eting with a good demand at very full prices for good and fine; other alities selling about steadily.
Brazil markets are somewhat lower.
Daily receipts averaged 9,100 bags in Rio and 9,000 bags in Santos.
Futures have fluctuated, closing dull at 6d per cwt. below the late hest, viz.:—Good average Santos in Havre, September delivery, fcs. 50, in Hamburg pf. $30\frac{1}{2}$, and No. 7 low ordinary Rio in New York $5.80.
To-day's London official quotations are:—

	May	July	Sept.	Dec., '98.	Mar.	May, '99.

TEA.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, dated May 6th, 1898, says:—

QUANTITY BROUGHT TO AUCTION IN LONDON FROM 1ST JUNE TO DATE.

	Indian.	Ceylon.	Java.
1897-1898...	1,533,105 packages.	1,107,575 packages.	41,399 packages.
1896-1897...	1,505,501 „	1,048,784 „	42,441 „

30,778 *pkgs.* INDIAN
23,999 „ CEYLON
684 „ JAVA
} Total 55,461 packages were offered in public auction this week.

The improvement in deliveries which set in during March, after the previous falling away, was still further emphasized by the satisfactory clearances in April.

Indian. Good general bidding kept the market steady in spite of another week of comparatively heavy offerings. Choice liquoring parcels further hardened in value, but poor Pekoes were occasionally a trifle easier. The Official Telegram gives exports for the second half of April as 354,000 lbs., against 276,000 lbs. last year, and from 1st April to 30th April 410,000 lbs., against 361,000 lbs.

SUBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly, ht Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including tage. Single Copies, Eight Annas.

ADVERTISEMENTS.—From the 1st October, 1897, the charge for advertisements will be: 4 as. per line for the first, 3 as. for the second, 2 as. for the third and succeeding insertions. Five-line advertisements m Subscribers will be inserted for three issues for one rupee; non-Subibers will be charged two rupees.

DOMESTIC OCCURRENCE.—The fee for inserting a domestic urrence will be *One Rupee* for each insertion, payable in advance.

N.B.—Remittances should be sent to the Manager, "Planting Opinion," 12, Second Line Beach, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been removed to Madras, all remittances should be made payable to the Manager of *Planting Opinion*, 11 and 12, Second Line Beach, Madras, who will also attend to all advertisements, &c.

Letters to the Editor should be addressed to Coonoor, as usual.

SEASON REPORTS.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 10th June, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nilgiris.

COONOOR, *2nd June.—Weather.*—The very favourable weather continues and is doing great good to all plantation and field crops. *Crops.*—Coffee is filling out, tea is flushing strongly, and field crops are growing well. Rain for past month 5 inches. *General Health.*—Health very indifferent still, several planters being down with a bad goes of acute fever. *Labour.*—Labour abundant. *Interesting Items.*—Luckily we don't get much S. W. rain here, so the unhappy railway *may* be opened before Christmas, but I strongly doubt it.

NOTES.

Japan tea in Russia.

It is grimly pleasant to hear that our rivals the Japs do not find the work of opening up new markets any easier than we do. Russia, into which they are trying to force a way, has not so far shown itself very keen on the change.

Produce imports into Britain.

Last month was a slack time for imports of plantation produce. Coffee fell off by £137,000, and tea by £79,000, but in cocoa there was an increase of £55,000, and in tobacco £93,000. Wheat, however, shows a great increase both from America and India.

Value of coal ash as a manure.

A correspondent recently asked us if coal ashes possessed any manurial value. The manurial value of ashes consisting almost wholly on the phosphoric acid and potash they contain coal ash, which contains only traces of potash, and but 0·16 of phosphoric acid cannot be said to be worth much as a plant food. Its mechanical value, however, may be great under certain circumstances. As wood ashes differ so widely in their manurial value, (from 3 to 35 per cent. in potash, and 0·45 to 2·03 in phosphoric acid) it is just possible that our correspondent's coal ash may likeuise differ from the ordinary variety.

To use ashes.

In another column we reprint an interesting article from a home paper on the value and use of wood ashes. The extraordinary value of swamp-elm ash (35·37 per cent. of potash) compared with the usual 4 per cent. sample, shows that it would be well worth while conducting investigations in the different values of Indian wood ashes.

Another point worthy of note is that ash should never be used with cattle-manure, or, we presume, any animal nitrogenous manure, as it tends to liberate the ammonia. It should be applied alone, as a top-dressing if possible. Its use on heavy humus-rich soil is usually most marked, as its "digestive" powers are quite as valuable in many cases as the direct food it affords to the plant.

Leaf disease in America.

We direct the special attention of our readers to an article from the Hawaian *Planters' Monthly* that we reprint elsewhere on a curious coffee leaf disease that is getting formidable in Guatemala. It is named *Stilbum flaridum*, and is a vegetable fungus well-known in Costa Rica, Venezuela and Jamaica. From the description given the fungus seems a very near relation of our fell enemy, *Hemaleia vastatrix*, if it is not indeed the real Simon pure. It first appears as a little brown spot, about the size of a pea, on the leaf. Many of these spots are sometimes found on each leaf. In the centre is a little orange red growth, about the size of a dot, which under the microscope appears like a little ball on a stem. Under the action of the fungus, the leaves shrivel up and drop off, and in consequence the berries act in a similar manner.

The Indian tea estimate.

The crop for the present season is estimated by the Indian Tea Association at over 158½ million pounds, being nearly 10½ millions over the actual outturn of last year. Estimating shipments to America, the Colonies and other places with local consumption at 18 millions, there will remain about 140½ million lbs. for export to Great Britain. Of the total, Assam is credited with nearly 64 millions Sylhet, Dovars and Cachar at from 22 to 26 millions each and Darjeeling at 8 millions. South India, as usual, is not represented in the above estimate, though the exports considerably exceed those of Chittagong, Chota-Nagpore, and Kangra, which are all found in the list.

The exports of tea in April from Calcutta are well below those of last year, but considerably higher again than in 1896. Ceylon exports from the beginning of the year are over 33½ million lbs., against almost 37 millions last year.

Edible mushrooms.

It will interest many to le that the "Round the Bungalo notes are continued, after a long interval, by "A Plante Wife." An interesting letter on how to distinguish edi mushrooms from those that are poisonous forms the subj of her paper. We do not believe, however, that there is a infallible guide or test that will enable the layman to p nounce with correctness on the edibility or poisonous nat of fungi. Nature has not, alas, taken any more trouble this matter than in others, to save mankind from trouble of acquiring knowledge. We would recomme our readers to make a thorough acquaintance with, say, th or four of the commonest varieties of edible mushrooms their district, and leave the rest severely alone. If ad to this they can recognize those poisonous varieties wh most closely resemble the edible ones they will do v well. Lastly, we may add that the most frequent cause cases of mushroom poisoning is not due to natura poisonous specimens, but to the intensely poison properties of all mushrooms if bruised or decayed in slightest degree.

The Ceylon Cacao disease.

An interesting *interim* report this disease has been issued by J. B. Carruthers, whose servi were procured last year by private enterprise. His inves gations have led him to the discovery that the main dise is a fungus, lodging on the bark and gradually destroyi the tissues of the stem, eventually killing the trace. Anot fungoid disease, and quite distinct from the bark disea attacks the fruit pods themselves and occasions a hea loss in crop, estimated at from 15 to 20 per cent. of yield of the affected trees. Mr. Carruthers suggests t one at least of the indispensable conditions (heat and mo ture) for fungoid growth, *i.e.*, moisture, could be remov by lessening the shade on cacao plantations. On the oth hand shade has proved most effectual in preserving cac from attacks of Helopeltis, though Helopeltis is by no mea so dangerous a pest as the canker.

As the report in question is deeply interesting from detailed description of the experimental steps taken investigating the disease, we publish a portion of it length in this issue.

Gathering tea seed.

Some planters have an idea t to allow seed to drop from the tr instead of picking it is a sure way of getting a badly g minating crop. As a matter of fact, this opinion is larg based on insufficient observation, having its rise from obse ing the behaviour of the first fallen seed from the tre which seed is usually empty and useless. Touching on t matter the Jorhat correspondent of the Calcutta *Plan* writes as follows :—

"Certainly at the very beginning of the seed season, say Sept ber-October, many seed fall that are not ripe, either being knoc down by birds or monkeys, also many seed with nothing inside th fall, and also bad seed ; so that the first seed brought in *picked off ground* is not nearly so reliable as that which is picked up later This is my experience of some years with Assam tea seed. Seed fall from the tree of its own accord later on than the above date give what I would consider a proof of its ripeness; in fact I never p my tea seed, but always shake it down. Of course tea seed left *some days* on the damp earth under the tree does not tend to impr it, and it should be picked up at once if possiple. Seed seems ripen very irregularly on tea trees, those seed at the very top of tree always being the last."

e coffee trade.

Last year business in coffee was anything but satisfactory to those ncerned in it, and reports from the centres of the trade the continent confirm this, says the *H. and C. Mail*, and can certainly confirm this as far as regards Indian nters. The importation of coffee into Holland was un-ecedentedly large, being as much as 1,415,093 bags. Its st remarkable feature was the jump in Santos coffee to 4,983 bags, the Dutch East Indies contribution being rdly more than that of ten years ago. Prices fell seriously Amsterdam, good ordinary Java dropping to 7*d.* per lb., d average Santos to 4*d.* at the close of the year. In ance coffee stocks more than doubled during 1897. At e port of Havre they were nearly thrice as large as at the d of the year as at the end of 1896. The Brazils furnished e major part of the increase. In the United States an itation is going on for a war duty on coffee, it being argued t the imposition of a duty of four or five cents a pound uld raise the value of the stocks in hand to that extent. was estimated at the beginning of last month that the ible supply in the States was 1,482,920 bags, compared h 940,606 bags a year previous.

---

ate sanitation.

There exists a deal of misapprehension in some quarters as to the itary state of cooly quarters on South Indian estates, the lgiri correspondent of a Calcutta exchange apparently ng out of his way to create a misleading impression as to facts of the case. The main object of sanitation and dical supervision generally being to preserve public alth, it is obvious that as long as the desired result is ained, it matters little what special means are employed. most of our South Indian planting districts, epidemics, h as cholera, small-pox, and the like, are almost invariably nfined to the villages and towns, the estates themselves naining singularly immune. Advantages of good natural inage, one of the prime essentials of effective sanitation, a pply of good water, and really very tolerable climate, com-ed with a few common-sense precautions, are the causes the above desirable state of things. Added to which, the neral rule of avoiding the concentration of cooly lines on one spot, and the small size of our estates make the k of the South Indian planter an easy one in sanitary tters. If such results can be obtained in the natural ler of things, where is the sense of prating about Govern-nt-appointed Doctor-baboos, sanitary inspectors and the e ?

It is a curious thing, but we have always noticed that if nan wants to growl against his district, he chooses as a dium a journal as far removed as possible from the ality, the sincerity of the complaint being usually in erse ratio to the distance at which it finds expression.

---

e Plague on Plan-ations.

With such an awful epidemic as plague, it is absolutely impossible for medical men or lay-men to pre-t its course in a continent like India. To an observant der of the daily papers, the odds seem slightly in favor of plague gradually penetrating through the length and eadth of the land, if the present unsuccessful methods of nbating the disease are not improved upon. The disastrous ect its advent would have on the planting industry, which industry necessitates the employment of a large and very ignorant body of unskilled labourers, should the disease gain access to the plantations, is not difficult to forecast. The inoculation scare, on spreading to Darjeeling, caused a great disturbance among the coolies, to the extent of some gardens being temporarily denuded of their labour. Luckily the scare passed off with the non-appearance of the plague. And as soon as plague and plague regulations invade planting districts, a general exodus will commence, fraught with disaster, if not ruin, to the industry.

Criticism on the present policy of dealing with the plague may seem out of place in these pages, but we cannot help reiterating the opinion that is daily gaining ground among the friendly critics of Government. And this opinion is that it is practically useless and worse than useless to initiate any panic-causing measures of dealing with the plague. Segregation may be excellent, inoculation may be an inviolable protection, but unless martial law is to become the rule in plague-stricken centres, these or any other similar measures will do more to spread the disease than if it were left to run its course, *unless the confidence of the people be gained first.* Very trite advice this, it may seem, but our worst blunders in India have been due to the unaccountable neglect of such obvious principles. To gain the confidence of an excitable, ignorant and fanatical population is no light matter, but nevertheless every nerve should be strained to attain that end.

The care of lamps.

In a certain household that I know, says a writer in the *Boston Journal of Commerce*, the lamps are a source of the greatest delight and comfort for they are always spotlessly clean, and they give a light that could not possibly be better or brighter. The reason for this is that the mistress, instead of depending upon any of her several servants to care for the lamps and clean them, herself bestows upon them the necessary attention. When these receive a thorough cleaning—once every six weeks—the reservoirs and burners are boiled in soda and water and dried before the fire, not on cloths, as these might have lint. The cloths that are used for the daily trimming and dusting are frequently boiled to remove the oil. The shades are polished, and the lamps filled every day.

The wicks of lamps will absorb more oil if they are thoroughly dried before putting them in the burners. To prevent the lamp from smoking, soak the wick in vinegar, and then dry thoroughly. Occasionally washing and boiling the wicks in soap and water, rinsing and drying thoroughly, is also a good plan. Every day the charred portion should be rubbed off with a piece of paper or cloth, and once a week the edge of the wick should be trimmed with a sharp pair of scissors. The wick will burn with an ever flame if it be cut straight across and slightly rounded at the sides. The reservoir of a lamp should be kept well filled, but, when not in use, the wick should be turned down to keep the oil from oozing up between burner and collar, greasing the outside and causing a disagreeable odour. When a lamp is lighted, however, it is best to keep the wick turned up to its full extent to prevent smoking.

To render lamp chimneys less likely to crack, they should be put in cold water which must be brought to the boiling point, after which they should be allowed to cool slowly

without removing from the water. Wash the chimneys in ammonia water, and wipe dry on soft towels that are free from lint; polish with tissue or newspaper. Rub brown spots with salt or whiting.

Kerosene has always an unpleasant odour, therefore it is better to use the best astral oil for dining-room and parlour lamps. Some housekeepers perfume these oils, but this is altogether unnecessary. Never mix two kinds of oil, for the light from such is bad. To make a lamp burn brightly, drop in the reservoir a pinch of salt or camphor.

Rock soil. Some time ago the question was raised in these columns of the cause of the extra fertility of those "pockets" of soil in rocky ground. It was left an open question whether this extra fertility was due to the accumulation of humus alone, or whether this accumulation itself had been caused by the decay of the minerals in the rock. When examining these pockets in a forest soil, the problem is somewhat complicated, but becomes very easy of solution when one observes the beginnings of these pockets in open bare grass or scrub-land. In some cases the pocket of rich would will be found in the hollow of a rock, which again will be surrounded by bare soil of little depth. The first steps at soil formation are easily traced. The pioneer of fertility, lichen, begins the work by boldly attacking the rock itself. As it decays, its fragments drop in the cleft, and on this slender layer of semi-soil, if damp enough, moss finds a a ready lodgment. From now the work of accumulation is fast. A stray seed, blown by the wind or dropped by birds, falls in the cleft, germinates, grins and decays. This process is repeated until the cleft is filled to its brim with rich soft mould. From this tiny patch of strikingly fertile soil, the observer will turn with some surprise to the perhaps bare soil surrounding the rock. Surely the very conditions that produced the deposit of mould in the cleft of the rock, exist in even more marked degree on the surrounding soil. To what is the difference due? A very simple cause will account for this. The rock protects the pocket soil from being washed away by heavy rain. The surrounding soil has no such protection, and a large part of the year's accumulation of vegetable matter is annually swept away by the monsoon rains. Some of our readers may think that we are expending somewhat more energy on the question than the occasion demands. But wait. There is always a useful moral to be drawn from the observation of Nature's ways. Pocket soil is extremely rich. We know how this soil is formed. Cannot we imitate the process on our plantations? It is the surface flow of water that is ruinous to the fertility of the land, as we have all recently had an opportunity of learning. Let subsoil drainage be encouraged to the utmost, and this wasteful surface flow is stopped. In other words, to revert to our illustration, we have changed the conditions of the bare soil surrounding the rock to those that govern the accumulation of rich soil in the pocket.

A soil microbe. After the general introduction our readers have lately had to the great family of nitrefying (nitrate-forming) and de-nitrefying (nitrate-destroying) microbes, it will interest some if they make the particular acquaintance of a curious individual microbe, bearing the big name of *Bacillus megatherium*. This remarkable individual possesses, apparently, double power of both rendering soluble and destro nitrogen, as it exists respectively in the crude forn humus and in the readily available form of nitrates. foreign correspondent of the Dublin *Farmers' Gazette* attention to some experiments carried out by M. Car landowner at Ellenbach, West Prussia, with some micr which he obtained from fertile soil, in order to asce their effect upon the growth of other than legumi crops. He selected one variety, unknown to him at time, cultivated it in a prepared liquid, and poured a s quantity into pots in which oats and white mustard planted, the result being the production of 10 to 35 cent. more yield than was obtained in pots not thus trea Afterwards he steeped his seed-corn in the microbe solu on a large scale, and obtained similarly encouraging res Since 1894 he has treated all his seed-corn in this mar Dr. Stoklara, Director of the Plague Laboratory, too the study of M. Caron's experiments, and ascertained the microbe to which such good results were attrib was the *Bacillus megatherium*, discovered some years by Bary, who was corroborated by Koch. He found the bacillus, when placed among nitrates, was a de-nitri but also that it decomposed organic matter contai nitrogen, converting the latter into a soluble form suit for plant food to the extent of 22 per cent., during a pe in which only 4 per cent. would be so converted wit the presence of the microbe. Dr. Stoklara carried experiments with barley, confirming the conclus arrived at by M. Caron, and he is now making resear with the object of discovering how the microbe effects transformation attributed to its action. A preparatio the microbe culture in the form of a dry powder has made, so that any farmer can try it. In this cou however, the failure of "nitragin" to realise the g results attributed to it in Germany, so far as it has yet tested here, is calculated to discourage trials of sir preparations. Moreover, the statement that the *Bac megatherium* is a de-nitrifier of nitrates, as well as a verter of organic nitrogen into some soluble form of element, suggests caution in the use of the new prepara except on very poor land.

North Travancore. In its issue of the 30th ultimo *Madras Mail* has an instruc leader on what a flourishing planting industry really m to the country. The instance in point is the marvello quick development of the Kanan Devans, North Tra core, through the agency of that colossus of plan companies, Messrs. Finlay, Muir & Co. Spurred by the int activity of the new company, which practically possess whole district, other companies and private planters following the example, and the result is that in a very years the Kanan Devans will be one of the premier plan districts in South India. In the Appendix to the U. I proceedings of last year, the area under tea in North Tra core was put at 2,000 acres. Before the end of this there will be, it is stated, as many as 10,000 acres of increasing to 30,000 in the next few years. This, if cor means that in the next four years an extra 3—4 mi pounds of tea will be thrown on the market, advancin 10—12 million in the next decade. A large acreage is being planted up in coffee. With their reported mi

erling to spend in the district, Finlay, Muir & Co. have turally made things hum, and the officials sit up.

Our contemporary writes :—

'The Madras Government has recently had under consideration an plication from the North Travancore Land planting and Agricul-al Society for the constructiion of a new road 10½ miles long from dinayakkanur to the foot of the hills at Kotagudi, to meet the mpany's aerial ropeway at that place. The case made out by ssrs. Finlay Muir & Co., the agents of the concern, was so con-cing that Government has agreed to pay half the cost of the d,—estimated at Rs.53,000 with bridges and Rs.42,000 without dges—provided the Madura District Board pays half the remain-, and the company concerned the other half. The District Board s already agreed to pay one-fourth of the cost of the road ; and it mains to be seen whether Messrs. Finlay Muir & Co. will be epared to do likewise. Meanwhile Government has deputed an cer to survey the proposed road and to prepare the necessary ns and estimates.

'The importance of the road lies in this, that it is a necessary link the line of communications between the new planting district and e Madras coast ports. The nearest railway station is Ammaya-yakkanur. Between that place and Bodinayyakanur, a distance 47 miles, roads already exist ; and though some lengths are in a ocking bad condition, the District Board has udertaken to put em into proper repair as far as its funds permit. From Bodi-yyakanur there is a bridle path and a ghaut track for pack animals d coolies up to Devikolam and Manaar, but communication is so d and difficult that at times it is found impossible even to carry enough food for the estate coolies, who consequently have had to sent down again in hundreds for want of grain supplies. Messrs. nlay Muir & Co., however, understand what self-help means. ey are now constructing a pucka road about 20 miles long rough very difficult country from Manaar to the top of the otagudi ghaut ; and down this ghaut they are tracing a bridle-path timated to cost some Rs.15,000. Their enterprise in this direction es not stop here, however, for they are going to lay a steam amway along the road from Manaar to the top of the ghaut, while, we have already remarked, they are going to construct a wire peway (driven by water-power or steam) down the ghaut itself. or these communications the agents have already sanctioned an penditure of something like £30,000, which is an eloquent proof their determination to spare no expense in developing their huge operties. But this sum is a mere flea-bite compared to the total pital sum that it is calculated must be spent in developing, plant-g and equipping the properties. There are now about a hundred anters in the district, mostly Ceylon men, a picked lot."

---

ina tea in China and America.

Consular reports from China on the subject of the tea trade differ in regard to tea prospects. While me of them point to renewed efforts and hopes on the rt of the Celestials in regard to their tea trade, others e not at all sanguine about the prospect of rehabilitating , says the *H. and C. Mail.* Amongt the latter is the report Mr. Carles, the British Consul at Foochow, who says the xport of tea from Foochow in 1897 was nearly sixteen illion pounds below that of 1896. At present the culti-ation of tea is scarcely remunerative. In the Kien Ning nd Yen Ping prefectures rice is said to be taking its lace. In the Foochow neighbourhood the sweet potato eceives more attention, and in remote tea districts the onsul hears of curing-houses being offered for sale to issionaries, but Oolong, Seu-moo, Souchong, and Pan-ong teas retain and in some cases improve their position. he competition for Oolongs, some Souchongs, and flowery ekoes is still very keen, nothing like them being produced n India. Mr. Carles cannot see how China can regain her osition in the tea trade, the importance of which to the ountry is far greater than might be imagined. The con-mption of tea in China is restricted even in the provinces, which produce it to a small class. Even in Fuhkien, outside the literary class and merchants, the majority of the people use tea dust of different grades, and in provinces where tea is not grown other leaves take its place. In England 6 lbs. per head of the entire population is the average consumption. In the Foochow province it is probably nearly 3 lbs. per head, even among the small fraction of the population who are tea drinkers. Some of the old faults of Foochow teas appear to have been eradicated ; but none of the new methods of preparing teas appears to have proved a complete success, from which we are to infer that the dirty methods affected by the Celestial still prevail. This of itself would be enough to drive Englishmen from the Chinese to the Indian article could they but realise the difference between the two modes. One sensible and direct step towards the resuscitation of Chinese tea is being taken by the local Government—the *likin* charges have been reduced. But even this reform has not been induced by any real desire for the amelioration of the trade. The provincial Government has reduced the charges because it was apprehensive that, if it made no concession, tea would be brought down to the coast under transit passes, the proceeds of which would not go to it, but to the central Government.

The American importation of Chinese tea in the year ending June, 1897, amounted to 56,932,000 lbs., valued at £1,467,000. This represents about half the total import of tea into the United States for that year ; the balance was contributed by Japan (45,000,000 lbs.), the United Kingdom (6,000,000 lbs.), and East India (2,000,000 lbs.). The total consumption of China tea by the United States in 1896 was larger than the British consumption by about 1,700,000 lbs., but fell short of the Russian consumption (inclusive of Asiatic Russia) by over 14,000,000 lbs.

Coffee and Tea Market.

Coffee.—The advance which took place in the terminal market last week has not been maintained, writes the *P. M. Review,* of 7th May, and quotations have gradually given way to the extent of 9*d.* to 1*s.* per cwt. No fresh news is to hand to cause this decline, and quotations in Brazil are unchanged, but there has been little desire to buy for forward delivery. The auctions have again been on the same extensive scale as the last few weeks, but as the demand continues strong nearly everything has been readily sold, and prices have been well maintained, while some kinds are rather dearer. Costa Rica, from 75*s.* to 90*s.*, has sold very freely, and is

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contain per ton :—

61·50	lbs.	Nitrogen.
57·38	„	Potash.
14·92	„	Lime.
13·68	„	Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the 1898-1899 crop of seed from the parent trees of above analysis at Rs.6 per pound containing about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere save from the

MANAGER, ARIENKOW ESTATE,

Shencottah.

from 2*s.* to 4*s.* above the recent lowest points, while Mysore has sold at fully 1*s.* advance. There has also been a larger business in Guatemala and other Central American descriptions, mostly taken for export, and several re-sales of parcels out of recent auctions are reported at 2*s.* to 2*s.* 6*d.* profit. The Dutch Trading Company have advertised their next sale for Tuesday, when 21,000 bags and 34 cases will be offered against 19,582 bags and 222 cases at the corresponding sale last year.

Indian Teas.—There was less competition at the public sales, and in some cases the tendency of prices was somewhat easier. This more particularly applies to the poor liquoring sorts, which are comparatively neglected, and a larger portion than usual was withdrawn from the sales. On the other hand, the more useful kinds, especially fine teas, were eagerly competed for, and an advance of ½*d.* to 1*d.* was established, which appears likely to be maintained for some time to come. The medium descriptions met with a fair demand at last week's prices, and, having regard to the smaller quantity coming forward, it is probable that rates will not show much change before the arrival of the new crop. For common sorts the market was somewhat irregular, and there was less difficulty in getting teas for price, but the slight change in value has not brought them to a level with the prices ruling before the rise on Monday week. Of course, this upward movement was due to an exceptional operation, and there appears to be no reason why it should affect prices for any length of time. The following figures for April, compared with those of the same month last year, are, on the whole, satisfactory. Imports were 1,560,000 lbs. and 1,297,000 lbs. respectively, while the deliveries were 1,541,000 lbs. more, the quantities being 11,154,000 lbs. and 9,613,000 lbs., and the excess in the stock is further reduced by 1,278,000 lbs. At the public sales 30,778 packages were catalogued and 3,971 withdrawn, which mainly consisted of undesirable qualities.

LETTERS TO THE EDITOR.

TO MAKE LIME JUICE.

SIR,—I should feel much obliged if you or any of your readers would give me a reliable recipt for making lime juice that will keep, like that manufactured in England and sold out here.

I have tried to find what I wanted in the back numbers of *Planting Opinion*, but can only find "To preserve lime juice" in your issue of October 10th, 1896.

Almost all the lime juice that one buys has a nasty flavour, is this caused by the necessity of putting in Salicylic acid to preserve it?

It seems to me absurd to buy English made lime juice w one has cartloads of limes on the place, if it can be mad the premises.

SANTAVERI, 27*th May* 1898. } ENGINEER.

STUMPING.

SIR,—In view of the approaching planting season and the l number of *E. lithospermas* that will be put out shortly, I sh like to advise all those who have large plants *not* to stump t They are far better put out when the weather is very and app likely to continue so. If the plants get a few days contin wet and dull weather they will usually grow right away,and if the weather clears, and they lose all their leaves, they almost invariably shoot lower down. Letting them die ba in any way preferable to stumping them, as the water gets d inside a stumped *E. l.* and promptly rots the plant, so if stu ing should be restored to then it is an absolute necessity to tect the exposed end from water lodging. There must be n good many *E. l's.* that are big enough now to be thinned lopped, and I would recommend strongly that the loppin buried fresh and green. They have an excellent effect on kee crop on trees benefit the trees generally.

In reference to the interesting accounts of green manurin Lupitz published in *Planting Opinion*, it would be interes to know whether lupins have been grown succesfully in co They have been tried, I know, near Ootacamund. The comp success of the "Lupitz" system is very gratifying as it was parent of "Coffee cultivation without manure."

ARIENKOW, SHENCOTTAH, 27*th May*, 1898. } B. NELSO

TEMPERATURE IN TEA DRIERS.

SIR,—It is generally assumed that the temperature show the thermometer in the drier is that to which the ro subjected. This is only so far true as regards the tempera of the heated air. But the roll comes in contact with galvanized or brass wire mesh, and in all up-draft driers mesh is very considerably hotter than that of the air. So an air temperature of nominally 220°, which is assumed truth to be incapable of burning tea, may and usually does a temperature of 250° to 260° on the surface of the wire ga Thus, while the upper layers of roll on the tray may be still and copper-coloured, the leaf in direct contact with the may be actually burnt. This of course is universally recogn to a certain extent by the frequent turning of the tea on trays. Tea is practically never fixed at such a low tempera as 210° (air heat), 240° to 306° and even over are the rule. such cases the actual tray heat is enormously in excess of registered temperature.

The remedy is of course obvious. The bulb of the thermom should be encased in wire meshing (the wire and the glass b in direct contact) instead of at present isolated from all cont If wire mesh is unavailable, a strip of tin or some other suit metal might be so placed as to touch the bulb.

The natural up-draft drier suffers a great deal from the fur fact of the heated air being unable to pass through the wire n even if empty of tea—with any degree of freedom. This is largely to the small size of the mesh employed, which m with great advantage be, say No. 10, instead of at present No to 16. Of course in cases where no provision is made by hop or other means for preventing the small tea that falls thro the trays from coming in contact with the furnace, such a cha would be impossible. Rather indeed should the size of the n in this instance be decreased to No. 20 or even smaller.

Have any of your readers used the Revolving Automatic Cyli drier, which seems to be made on even more scientific princi

Davidson's Travelling-web Sirocco. In these days of fierce petition we cannot afford to let the quality of our tea depend nuch as it does at present on at best more or less unreliable an labour.

TEA DRIER.

GENERAL ARTICLES.

MORE ABOUT WOOD-ASHES.

E learn from a report by R. Harcourt, B. S. A., Assistant Chemist, C., Guelph, that there is a growing interest in the subject of d-ashes, and their use as a fertiliser. This is largely owing to fact that long cultivated lands are beginnnig to show a lack of lising constituents that are supplied by ashes, and to a desire on art of the cultivator of the soil to increase and improve his crops. e growing plant gathers all its mineral constituents from the in which it lives, and these, now being combustible, are left as when the plant is burned; consequently, the ash must contain all mineral constituents that are esential to growth. These are sh, phosphoric acid, lime, magnesia, iron, and sulphur. These tances form a very small part of a plant, yet without them no t could grow and produce seed; in fact, they are indispensable ife. Of the six essential plant-food substances named, potash phosphoric acid are the most important, not only because they taken up by the plant in large quantities, but also from the that our average soils do not contain them any too abundantly. d-ashes, therefore, are usually valued according to the amount ose two constituents which they contain. Although potash and phoric acid are the most valuable plant-food substances in ashes, shes also contain large quantities of lime, which is of consider- value to the growing plant. Lime is usually present in most len soil in sufficient quantities to supply the wants of plant- vth, yet its application may produce marked effects. By acting nically on certain constituents in the soil, plant-food, especially sh, is brought into an available form. It neutralises the free of the soil and thus helps along the process by which vegetable ter is changed into a form in which the plant may make use of nitrogen. It also tends to improve the mechanical condition of clayey and sandy soils.

he amount of these fertilising constituents contained in an ash vary according to the source from which it is derived. The ash young branches will be richer in potash than that from the r parts of the tree. Different soils will supply varying quantities otash, phosphoric acid, and lime. The following table gives the oosition of a few of the more common ashes analysed by Mr. court. The figures given express the percentages of the various tituents in the dry ash:—

Constituents in Wood-ashes per Cent.

Ashes from	Potash.	Phosphoric Acid.	Lime.	Magnesia.	Iron.	Sulphuric Acid.
le	9·31	2·03	45·24	...	...	1·14
h	7·58	1·39	41·21	6·16	0·3	traces
r	3·30	0·98	49·06	2·49	0·70	0·77
mp Elm ...	35·37	0·45	23·64	6·48	0·19	traces
k-ash	25·30	1·20	49·04	7·42	0·22	0·71
l coal	traces.	0·16	traces.	...	5·32	0·41

he figures show clearly why ash buyers are so anxious to get black or swamp elm-ashes, but at the sametime, it must not be for- en that these ashes are very light and bulky; consequently, there be more potash in one measured bushel of hard maple ash than he same bulk of swamp elm-ash. The hard woods contain a larger quantity of phosphoric acid than the soft woods. Cedar, as would be expected, is poor in both potash and phosphoric acid. The best way to ascertain the true value of ashes is to note the increased yield when they are applied to crops requiring potash, such as potatoes, carrots, grape-vines, and fruit-trees generally.

The caring for and application of ashes must receive special attention. If not properly stored while accumulating, much of the soluble plant-food will be lost by leaching. If not applied to those plants which are in special need of potash, no noticeable results may be obtained. Further, if mixed with farm-yard or stable manure they may do more harm than good, because they tend to liberate, as ammonia, the nitrogen of the manure; If we may judge by the amount used by fruit-growers in the best fruit districts of the United States and Canada they are fully aware of the value of wood-ashes in the orchard.—J. J. WILLIS in the *Gardeners' Chronicle.*

PINEAPPLE FIBRE.

THE United States Department of Agriculture has recently communicated a special report on the subject of pineapple fibre.

In preparing the fibre, the green leaves are steeped in water for some days, as they become unmanageable if allowed to dry. The native method of hand preparation is to lay the leaf upon a board and remove the epidermis and succulent matter with any suitable scraper. A two-handed bamboo plane is used in China, while in the Philippine Islands the blunt end of a potsherd is employed. When the epidermis has been removed, the fibres are exposed, running in a longitudinal direction. Another worker now takes the planed leaves, and loosens with his thumb nail the fibres near the middle of the leave and, gathering them in his hand, detaches them from the outer skin. The fibre is very fine and soft, the filaments being quite flexible and resistant; they yield readily to treatment in an alkaline bath, and are easily subdivided. After separating from the skin, the fibre is steeped in water, washed, and laid out to bleach on wide frames of split bamboo. The processes of washing and exposure to the sun are continued until the fibre is considered to be properly bleached. The isolated fibres are now very fine, and of a tolerably regular diameter, although varying considerably in size, the interior canal being very noticeable in the larger, but almost absent in the smaller, ones. The points are rarely sharp, but generally rounded.

It is claimed for pineapple fibre that constant immersion in water does not in the least injure it, and the natives tan it, with a view of increasing this property, though this is probably done at the expense of some of its strength. The fibres are very flexible, curling and twisting readily. Although naturally fine, the bleaching process, which destroys the adhesion between the bundles of fibres, renders it so much finer that it can be spun like flax. Both the wild and cultivated pineapple yield fibres which, when spun, surpass in strength, firmness and lustre those obtained from flax.

For the manufacture of sewing thread, twist, curtains, etc., its particular qualities render it specially applicable.

In tests of strength, pineapple fibre exhibited superior tenacity. The fibre from Singapore bore a strain of 359 lbs. as against 250 lbs. borne by New Zealand flax. This latter is considered superior to the highest grades of English hemp. In the *Journal of the Agricultural Society of India* (Vol. III., p. 182), there is a record of a rope of pineapple fibre, $3\frac{1}{4}$ inches in circumference, bearing a strain of 5,700 lbs. before breaking.

In the East Indies, where the pineapple was introduced as early as 1600, the fibre is exclusively employed in the manufacture of the delicate fibre known as "pina" as well as for cordage. "Pina" is considered more delicate in texture than any other product manufactured from vegetable fibre. It is woven from untwisted fibres, after they have been reduced to extreme fineness, and have had the ends glued together to form a continuous thread. The plant is specially grown in the Philippines, and it is customary to remove the fruit before maturity, so that the leaves may be more fully developed. Where the industry to be established commercially, it is certain that the tedious process of hand preparation would be superseded by machinery. Several machines have been invented, and Spon describes one by Sanford and Mallory, which cleans, it is stated, from 6,000 to 8,000 leaves per day.

The machine used by Mr. Dodge, the author of the United States' Report, was one by Van Buren, which, while turning out a superb

product, would be quite inedequate for the work from a commercial standpoint, as only two or three leaves can be fed in at a time. The Florida fibre, when simply plunged into cold water for a few moments after coming from the machine, and then dried in the sun, came out almost white and of a fineness and softness unequalled by any other leaf fibre with which the department had dealt.

Quotations as to value are not at present available, as the fibre is not yet a commercial product. There seems no doubt that if the fibre could be produced in quantity, at economical cost, manufacturers would readily find use for it. The question as to a suitable machine, enters largely into the problem. Estimating ten leaves to a pound, there would be over 22,000 leaves to the ton, from which about 50 to 60 lbs. of fibre is obtainable. The Sanford and Mallory machine, capable of clearing 5,000 to 8,000 leaves a day, would only produce 12 to 18 lbs. of fibre; this would make it somewhat high in price. The United States Department of Agriculture intends to carry its experiment with pineapple fibre further, as to give manufacturers opportunity of examining it. It may be added that the value of Indian pineapple fibre is being ascertained, and its characteristics investigated in the Scientific Department of the Imperial Institute.—*B. N. B. Herald.*

CACAO DISEASE INVESTIGATIONS.

INTERIM REPORT BY J. B. CARRUTHERS.

IN this report I propose to confine myself almost entirely to a statement of observed facts as far as they seem at present to lead to a knowledge of the cacao disease; but many facts observed are unrecorded here, and may at a future time be of use when a final and fuller report on the investigation is submitted.

Leaving England at short notice I had no time to make myself acquainted with any literature which might bear directly on these diseases of cacao if any such exists, and, therefore, on arriving here began *ab initio* in my researches into the cause of the deterioration and death of the diseased trees.

The Director of the Royal Botanic Gardens very kindly placed at my disposal the result of his observations on the disease, as well as all the information he had accumulated from planters and other sources, and the two most valuable circulars issued by him showed me the knowledge of the disease possessed by planters up to that time.

At the estate where I began my work I was fortunately able to see diseased trees of all ages, both of Forestero and Red Cacao, and had every facility given me for experimenting on these and on healthy trees.

The fact that trees of all ages, from three or four years upwards, in the best and richest soil and in favourable aspects, were attacked, and that trees apparently in a most healthy condition became victims to this disease, pointed to its being the result of extraneous parasitic organism—either plant or animal—no animal injuries could be found *exclusively* on diseased trees, and therefore the supposition that it might be due to a fungus was a fair one, and I at once proceeded to learn if this was the case by discovering the fungus and endeavouring to induce it in a previously healthy tree.

The conditions favourable for the growth of fungi are moisture and heat; the latter of these is always sufficient in this country, but the former is more occasional. At the time of my arrival the north-east monsoon was providing a time most advantageous to fungi, and I spent the first week in collecting and examining all the fungi I found upon the cacao tree. Here I may say that one of the difficulties in an investigation of this sort is the very large number of fungi to be found in the cacao like all other plants, which are either saprophytic, *i.e.*, living on dead trees or dead portions of a tree, or merely superficial, like the lichens. Both these classes are of little interest in this investigation, as the former, though often occurring with the disease, are an after-effect, appearing when the damage is done; and the latter have, as a rule, no effect whatever on the health of the tree. But the difficulty lies in distinguishing between these and the parasitic fungus which is the real cause.

In order to discover the nature of a fungus and to learn its life history, it is necessary to observe its reproductive organs, just identifying flowering plants the flower must be found. Two me can be followed in such a research, either to discover the fruit fungus in the field (and this is naturally a not very easy m owing to the small size of the reproductive organs of fungi) place some of the mycelium or roots of the fungus under cond most favourable to their reproducing themselves, and keep under close observation.

The difficulty in this latter method, especially in this coun the large quantity of bacteria, torulae and other organisms wh is almost impossible to exclude from the cultures and which de the fungus under observation.

In the case of the cacao disease it was necessary in the first to form some conclusion as to portions of the tree affected. examination of the roots of badly diseased trees showed no sig fungus, and other facts of importance in this connection are trees, which are badly attacked, if cut down to within a few i of the ground will produce from the remaining portion of the suckers which are perfectly healthy and produce sound leave fruit; also that seedlings planted only a few inches from a diseased tree—so that their respective roots must be intermatte touch at many points—grow vigorously without any signs of di These facts lead me to the opinion which, I think, I shall fa prove in this report that *the disease does not affect the roots.*

On coming to the examination of the stem and branch disease trees, patches on the bark can be observed with the eye, in some places claret-coloured drops exhume from the bark where these drops had presumably run over the surface, a char istic rusty skin is produced, the patches were darker in colou damp to the touch, and on cutting into them the tissues are to be discoloured, their natural colour being changed to a ne tint or claret colour. On examining these portions microscop the tissues are found to contain the mycelium (that is the veget portion) of a fungus, and also in large quantities bodies of m less spherical shape, the nature of which I at first thought fungal, though a certain resemblance to the rest spores found a certain groups of these plants—they, however, can be dissolv hydrochloric acid, and therefore I consider them to be clu crystals of oxalate of lime, the nature of which I am investig and hope to elucidate. These bodies, however, have no conne with the fungus and are therefore of less importance.

The leaves are free from fungi and, in cases of a tree having from disease, present all the appearances, on microscopic exa ation, that the leaves of a tree dying from want of moisture w have, thus showing that there is no disease in the leaf, but that death of the stem having cut off the supply of nutrition from root, the leaves have died with the rest of the tree.

On coming to the fruit I noticed a very large number of dea diseased pods of all sizes from an inch long, many of which covered with saprophytic fungi and had died from causes wh hope at some future time to discuss; but others—and these larger ones—were attacked by a disease which, from its occur on trees otherwise absolutely healthy and from its non-occur on cankered trees, came to the conclusion it has no connection the canker, and the experiments which are afterwards desc support this view.

The disease can easily be distinguished from the blackeni pods owing to drought or Helopeltis. It begins either at the or at the stalk of the pod, almost never (about once in a hun in the middle, and creeps along the pod showing a well-de boundary of brown tissue encroaching on the yellow, red or g healthy tissues of the pod. If the pod is cut this will be fou discolour the whole of the tissue not to be merely a super injury as in some other cases of browning or blackening.

The damage that this pod disease has caused in Ceylon I ca yet say, but where I have observed it, it has probably produ loss of 15 to 20 per cent. of the annual crop by attacking pods were approaching maturity, and if the number of young pods l and never picked were included in this estimate the figure wou much higher. This percentage is for the whole year; during wet season—favouring the growth of the fungus—more lik per cent. of the crop was destroyed or rendered of much inf value.

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

A microscopic examination of the discoloured tissue showed the antities of mycelium, which was larger and of a different character m the mycelium in the stem, and a portion of it was placed under servation in a culture apparatus. After a few days the mycelium gan to produce branches at the end of which egg-shaped bodies e borne. These egg-shaped bodies are seen to contain circular lies, and are no doubt the sporangia or fruits of a fungus which long to a group of plants, the greater number of which are rasites in the tissues of flowering plants and to which the well-own potato disease belongs.

A few days later I was able to confirm these observations by lecting from a pod in the field these same reproductive organs the surface of the pod.

The fruit of this fungus can be easily recognised by the naked eye a white mould occurring chiefly in the furrows of the pod. The pidity with which the fungus completely permeates the com-ratively soft tissue of the pod is shown by the experiments orded later, and an important economic factor in dealing with s evil is that, after the pod has been well attacked by this fungus, further nutrition reaches the seeds and they are found to undergo increase in size. In the case of the younger pods where the ds are still touching the husk, the fungus spreads into and stroys them, but if the pods have approached to that point of eness when the seeds are free from the sides of the pod then the celium of the fungus does not cross the space and the seeds are touched.

Having thus examined the whole tree and come to the conclusion t the stem was the seat of the disease causing the death of the es, I began to watch carefully for any outward sign of a fungus ich was causing the canker, but for some time without success. lso carried on many cultures of diseased bark in the hope that I ght get the fructifications under these artificial conditions. All se cultures, however, fell a prey to the enemies I have mentioned ore without having produced any reproductive organs.

However, on January 24th, I found a white excrescence on the kered portion of a red cacao tree, and on microscopically mining it found it to consist of a mass of mycelium bearing l-shaped thin walled bodies which I placed under hourly mination in a drop culture. In the course of 12 to 15 hours se bodies began to push out tube-like processes in diameter ut a quarter the breadth of the oval bodies.

The processes in some cases grew more than ten times the length he oval body in 18 hours; many of them sent out two tube-like cesses, in some cases, three, and these frequently coalesced so a string of two or more up to six or seven were all growing into tube. These tubes grew and branched frequently, and after 50 rs produced some smaller branches slightly conical in shape, at end of which were a number of spherical bodies, which, after a hours, were seen to consist of bodies of the same shape as the inal spores, and these in their turn pushed out tube-like pro-es in the same manner as previously described.

hese facts leave no doubt that these oval bodies are *spores.* res are the portions of a fungus capable of producing a new vidual, and they may for practical purposes be considered as the ls of a fungus.

During the few weeks following the discovery of these white rophores on the bark of the cacao, I found them on many trees ifferent parts of the estate, and collected and examined a large unt of material. A fortnight later I found a sporophore which tained bodies of a different kind to the previous spores. These bodies were about six times as big as the former spores and cent shaped or in the form of a bent cyclinder and usually 8 tate—*i.e.*, divided into 8 or less compartments. On placing these ies under conditions favourable to their development they pushed tubes from one or more of their compartments, and these tubes w and branched until destroyed by bacteria and microscopic ani-s. In some cases in one sporophore I found both these spores urring; the smaller oval spores forming the mass of the outside ne sporophore and only a few of the larger spores occurring.

s is well known to students of mycology, the fact of these two ls of spores does not necessarily point to there being two fungi, many fungi produce different kinds of reproductive bodies, and observations lead me to expect that in this case there will be a d kind of spore which will be found and will complete the reproductive bodies produced by this fungus. But as I wish this report to deal only with observed facts, I will not enter into any details with regard to this third form of spores.

With regard to the experiments which have been occupying my attention. In the first place I experimented with the pod disease and in the following manner: I took a number of pods in different stages of ripening and inoculated them, inserting into a small space previously cut a piece of diseased tissue taken from another pod. I put the diseased portions in at varying depths and at different parts of the pod—thus, one was near the stalk and almost superficial, and another was much deeper and half way down the pod. In all the pods the disease was speedily induced, and in some of them in five days the whole pod became brown and the tissue full of the mycelium of the fungus. Those pods that were inoculated near the end of the pod took the disease soonest, and as might be expected, where they were inoculated more deeply it began first. After some 8 days the spores of the fungus were produeed in the furrows of one or two pods. From these facts we learn that the time taken for the disease to destroy the pod is comparatively short (as is the case with most fungi inhabiting soft tissue,) I should estimate about ten days from date of attack, and much less than that from the time the disease is first noticed on the pod.

(*To be continued.*)

THE GUATEMALA COFFEE DISEASE.

Frequent reference has been made in our exchanges to a new and very dangerous disease which has attacked the coffee plantations of Guatemala and other parts of Central America and the West Indies. In last year's volume of the *Planters' Monthly* (page 230, May, 1897), will be found a letter referring to this disease from Mr. W. J. Forsyth, who visited these islands some ten years ago, and wrote a full report for the Government regarding coffee planting in Hawaii. His last year's letter did not furnish a full description of the Guatemala disease, but it contained the opinion of the Government Entomologist at Washington that it was what is called *Stilbum flavidum*, a disease that is well known in Costa Rica, Jamaica and Venezuela, for which he could suggest no remedy. Owing to this disease, Mr. Forsyth was compelled to abandon his plantation in Guatemala, and went to Mexico, where no disease to the coffee has yet appeared. His letter referred to above should be read by those engaged in coffee culture.

In the *Advertiser* of a recent date, Mr. Marsden, Commissioner of Agriculture and Forestry, publishes a communication, in which a more detailed account of this dangerous disease is given, from information received from Washington. We insert the whole of his article, and would caution coffee planters to be on their guard and note its first appearance, should it by any means reach these islands. If introduced by the seeds, the seat of the disease will probably be found located in the roots, and every plant found diseased with it should be dug up by the root and burned, root and branch, as the surest remedy, till something better is found.

I would respectfully call the attention of coffee planters to a fungus disease that is seriously affecting the coffee plantations in Guatemala. The following account of this disease has been sent to this bureau from Washington:

"It is a vegetable fungus which is destroying the coffee culture of Guatemala, so that the whole industry in that country is to be given up, unless a remedy is found.

"So far no antidote has been found for this fungus, nor any means by which it can be kept in check. It not only attacks coffee trees, but other plants as well.

"It is first seen as a little spot, about the size of a pea on the leaf. There may be a number of such spots on a single leaf. In the centre of each spot is a little orange red growth, about the size of a dot, which under the microscope looks like a little ball on a stem.

"The action of this fungus on the coffee tree is to cause the leaves to shrivel up and fall off, so that the tree is entirely denuded of its foliage, the growing berries also dry up and fall off.

"This fungus clings to seed coffee and may be transported to other countries receiving such seed."

It would be a wise plan for our coffee planters to refrain from importing seed coffee from any foreign country and any seed coffee

for which orders have previously been sent, should be disinfected as soon as possible after being landed on the wharf. This can best be done by immersing the bags containing the coffee in strong lime water, made by putting a large bucket or unslacked lime into 50 gallons of water. After the lime is slacked it should be well stirred up, and the bags of coffee should be immersed in the mixture for at least ten minutes. This method will effectually destroy any fungus pores that may be adhering to the bags or seed.

There seems to have been a great and general desire on the part of the coffee planters to obtain coffee seed from Guatemala and other countries.

There is no doubt but that the trees grown from Guatemala seed have borne crops much earlier than trees grown from Hawaiian seed; but it is by no means certain that the superiority of the Guatemala trees is maintained as the trees become older. As a general rule, trees that bear at an early age, soon lose their vigor and are short lived. We would like to hear from Mr. J. M. Horner on this subject. He was perhaps the first planter to grow the Guatemala trees.

J. MARSDEN,
Comr. of Agr. & Forestry.

—Planters' Monthly.

ROUND THE BUNGALOW.

NOTES BY A PLANTER'S WIFE.

Mushrooms. WITH the welcome showers of rain during the last week or two have come one of Nature's most delicious edibles, viz., the mushrooms. I fear many people refrain from eating them for fear of getting a poisonous one; the following, however, will enable one to tell the poisonous from the good. The small white topped pink gilled mushroom of the open is of course the most delicate, but the yellow topped and grey gilled, though coarse in flavour, is not to be despised or rejected as of doubtful character. In both, the cap is fleshy, and the gills quite free from the stem round which on the under side an open channel runs. This is a salient feature of an edible mushroom, as all the poisonous sorts have the gills touching the stem. The cap at the outer circumferences, further laps over the gills, and is pendulous, which is not the case with the cap of a poisonous mushroom, which terminates at its juncture with the gills. The stem should, moreover be solid when cut through, and have a collar round midway between the cap and the root. No poisonous or doubtful mushroom will possess this collar. The cap is sometimes silky, sometimes hairy, and sometimes scaly, all points perfectly consistent with wholesomeness, and should be dry, and never viscid, which is an unmistakable indication of noxiousness, the colour may be white, or tawny or dark brown. The colour of the gills may be white or pink, or salmon, or brown or even black, and the spores of the gills purple or brown, or black. The gills of poisonous mushrooms never grow black, however long they may be gathered, and the flesh of the cap never changes colour. The horse mushroom, as its name suggests, is of large size and springs up in clusters, a condition of growth which is said to be peculiar to the harmful varieties, but not always so. This variety affects the neighbourhood of trees or hedges and woods, but cannot for this reason be rejected as doubtful.

A mushroom presenting all the salient features which have above been described may be safely eaten either in a raw state or cooked, but if the consumer will neglect what has been said, and partakes of whatever is offered to him as a mushroom, he may pay the penalty sooner or later, of his want of caution.

It is a generally accepted truism that mushrooms which grow under trees are dangerous, because they are supposed to feed on decayed roots; but the mushrooms of the Nilgiri Sholas are an exception to this rule for some of the best and most delicate sorts are gathered under the shade of the forest.

An easy way of telling if there is a poisonous mushroom among a quantity is to put a small white onion with them in the cooking vessel when cooking them, if there is one poisonous mushroom the onion will turn black, and the whole dish should be rejected as unfit for food. I hope in another letter to give some food recipes for cooking mushrooms, which may be new to some of my readers.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (May 13, 1898) say: A steady demand still continues at Public sale in spite of very h supplies, and the market on the whole is well maintained.

About 3,500 East India were offered, chiefly composed of small which sold steadily at about previous rates whilst one or two fine parcels realised full values.

The large quantities of Guatemala and Columbian catalogued attra good competition in most cases, and all desirable qualities were disp of at very full prices; common descriptions however were occasio 1/- cheaper.

Futures have been rather firmer this week on reports of damag frost to the Santos crop and quotations show a slight advance since last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Market the Week ending May 11th, 1898, says:—Bank rate 4%. Bombay Exch closes at 1s. 4d. Brazil Exchange 5 5/32d. Rupee paper 3½% 62¼. S 26 1/16d. per oz.

This market has again been freely supplied, chiefly with Central A can kinds, which continue to meet with a good demand, especially fo better qualities. The moderate supply of East India, consisting chie small lots, sold steadily. Brazil markets are inactive.

The Dutch Sale of 21,013 bales Java, 34 cases and 7 bales Padang in Rotterdam yesterday, went off with good competition at an irreg advance, good ordinary Java selling at 332 cents, against 33 cents a April sale.

Daily receipts averaged 7,700 bags in Rio, and 9,200 bags in Santos

Futures have been steady but quiet, and close about 3d. per cwt. de viz:—Good average Santos in Havre, September delivery, fcs. 37.5 Hamburg pf. 31, and No. 7 low ordinary Rio in New Work $5.90.

To-day's London official quotations are:—

	May	July	Sept.	Dec., '98.	Mar.	May,
SANTOS ...	29/3	29/6	30/3	30/9	31/3	31/

TEA.

Messrs. Gow, Wilson and Stanton's Indian, Ceylon, and Java Tea Report, ed May 13th, 1898, says :—

QUANTITY BROUGHT TO AUCTION IN LONDON FROM 1ST JUNE TO DATE.

	Indian.	Ceylon.	Java.
1897-1898...	1,547,944 packages.	1,129,855 packages.	42,375 packages.
1896-1897...	1,521,710 „	1,073,781 „	43,928 „

365 *pkgs.* INDIAN
278 „ CEYLON
564 „ JAVA
} Total 55,461 packages were offered in public auction this week.

The quantity of British Grown Tea taken in places outside the United ngdom during the first three months of the past four years was as ows :—

1898.	1897.	1896.	1895.
. 11,904,523	13,150,910	9,218,946	5,660,970

All exceptional quantity of Indian Tea appears to have been taken ring the first three month of 1897, very little Tea being usually exported ect from Calcutta to foreign markets so near the close of the season.

Export of Indian and Ceylon Tea in lbs. to places outside the United Kingdom from 1st Jan. to 31st March.

Ceylon. The week's offerings were again light, the Teas being in consequence very readily absorbed by the trade. Bidding for all descriptions was animated, Teas of really good quality selling at if anything slightly better prices, while for all other grades the recent advance in price was well maintained. The auction was assisted by a good shipping demand.

Average price is 7·72d. against 7½d. same week 1897.

Ceylon Tea sold on Garden Account 1st Jan. to date 1898,416,692 pkgs., av. 7·64d. 1897, 380,558 pkgs., av. 7·93d.

"Englishman," August 1st, 1896.

APPRECIATION OF AN INDIAN MIXTURE.

Messrs. CHILD & CO.,

The Wholesale Tobacconists of Chowringhee, are in possession of an autograph letter from Mark Twain.

"Indian Daily News," August 1st, 1896.

Mark Twain left a substantial memento of his visit behind him in Calcutta in the shape of a letter addressed to Messrs. Child & Co., and an old Mississippi pilot knows what good tobacco is, even when he takes to literature.

MARK TWAIN.

Calcutta, February 8th, 1896.

MESSRS. CHILD & CO.

SIRS,—This is the brand I wanted. I have smoked your Honey Dew Mixed in another part of the world, and learned to prefer it.

Truly yours,
S. L. CLEMENS.

CHILD & CO.'S HONEY DEW MIXTURE

Is prepared from the four finest growths in world, *viz.* :—

Sun-dried Virginia (sweet and mellow), Old Kentucky (flavoured), Turkey Dubec (mild), Latakia (fragrant). All fi matured in bond, and judiciously blended.

It is a faultless Pipe Tobacco, being of medium streng

WITH DELICIOUS FLAVOUR.

THE FINEST THAT CAN BE MADE. NO EQUA

In ¼lb. air-tight tins, Rs.2-8 per lb.

egulated by Act No. VI. of 1869 of the Legislative Council of Fort St. George

Invested Funds exceed ... Rs. 22,00,000 | Gross Annual Income exceeds ...Rs. 3,00,000

BOARD OF DIRECTORS.

ne Hon'ble Mr. GEORGE G. ARBUTHNOT, (Arbuthnot & Co.,) Chairman.
UTHERLAND ORR, Esq., (Barclay, Orr & David.)
W. GORDON, Esq., (Mercantile Bank of India, Ld.)
A. ROBERTSON, Esq., (National Bank of India, Ld.)
R. J. BLACK, Esq., (Best & Co.)

Medical Adviser.—Surg.-Lieut.-Colonel J. MAITLAND, (Actg.)

ctuary—RALPH P. HARDY, Esq., United Kingdom Temperance and General Provident Institution.

he chief characteristics of this Society are:—

Mutual Assurance; consequently all surpluses are divided among the lives assured exclusively.
Immediate payment of death claims, an official notice in any of Her Majesty's Government Gazettes being sufficient proof.
Surrender value allowed for Life Policies issued at fixed rate of premium, on which 3 years' premiums have been paid.
Agency in London for receipt of premium $\frac{\text{and}}{\text{or}}$ for payment of death claims.
On Policies transferred to the London Register, death claims will be paid in England at the current exchange on Madras without production of Indian Probate or Letters of Administration. Premium may be paid in London at 2*s.* per rupee or it may be remitted direct to the Secretaries and Treasurers by Demand Drafts on Madras.
The Society's Funds invested in India Government Securities only.
Directors must be residents at Madras.
Members consist of all holders of policies either on their own lives, or on the lives of others, for the duration of life.
General Meetings held Annually—not later than the end of March, in every year.
Auditor elected by Members. Accounts audited Annually.
Valuation of Society's affairs must be made quinquennially.
The reduction for the quinquennium 1896—1900 is at the rate of 75 per cent. of original Annual premiums paid during 1891—1895. Thus the premium on a policy for Rs.10,000 on the life of a person, aged 34 years, Civil Rates, on which the original half-yearly payment was Rs.225 during 1891—1895, is reduced to only Rs.56-4-0, or say, to one-fourth of the original half-yearly payment during 1896—1900.
Term Policies issued at moderate, non-participating Rates.
The Medical Adviser sees applicants for Assurance at his residence, "Fallowfield," Royapettah, on Mondays, Wednesdays and Fridays, between the hours of 12-30 and 3-30.
For Prospectuses, forms of proposals, &c., apply to

.B.—Remittances should be sent to the Manager, "Planting Opinion," 2, Second Line Beach, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been oved to Madras, all remittances should be made pay- to the Manager of *Planting Opinion*, 11 and 12, ond Line Beach, Madras, who will also attend to all ertisements, &c.

Letters to the Editor should be addressed to Coonoor, usual.

SEASON REPORTS.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 17th June, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Coorg.

POLLIBETTA, *8th June.—Weather.*—The weather has, for the past few days, been monsoonish, but very light, mostly like a "Scotch mist." The precipitation of moisture is very small. *Crops.*—Berries swelling. Estimates on blossom mostly reduced; but crops are still very fair. *Works.*—Removal of borer and supplying going on. *Labour.*—Estates are fairly well supplied with labour for the time of year. *General Health.*—Good.

Nilgiris.

COONOOR, *8th June.—Weather.*—The S.-W., or what looks very much like it, monsoon made its appearance here on the 6th, in the shape of fairly strong S.-W. winds and a driving thin rain. Weather for both coffee and tea is most favourable, and no improvement could be wished for with respect to either.

KULLAKAMBY, *8th June.—Weather.*—The S.-W. monsoon broke here on the 5th with strong wind but very little rain; the weather, however, has been cloudy ever since with heavy mist. *Crops.*—Second blossom out on most estates, and coffee looking very fit. *General Health.*—Fever still very prevalent among both Superintendents and labour. It is hoped the strong winds and general change in the weather will check malaria. *Interesting Items.*—Tigers and panthers have visited several estates, and several kills have occurred.

NOTES.

Creepers and tea.

"If plucking tea," says an old Ceylon planter, "is no longer as remunerative as formerly, yet there can be no doubt that plucking creepers is still as profitable as ever, as the import seems to show no falling off."

The Zanetti vine experiment.

Mr. Zanetti, the gentleman who has been conducting an experiment in growing Australian vines at

Colombo, under certain terms with Government, has now had to give up the trial. It is a great pity, as the vines were doing exceedingly well, and had the experiment been continued for a few years, a valuable industry might have sprung up. We wonder, by the way, that the Bangalore experiments are hanging fire as they do. Surely enough experience should have been gained during the last ten years at least to justify the planting up of experimental vineyards on a fairly large scale.

South Indian Teas. Arrivals were not so heavy with Messrs. Arbuthnot and Company's Monthly London Report of 13th May, 1898, and at the auctions only 2,700 packages were brought forward, which realised 6*d.* per lb. compared with 6¼*d.* per lb. for 5,849 packages in March. Several of the shipments from Travancore were of useful character, among those realising the best averages being Bon Ami, Glenmary, Pambanar, Arnakel, Penshurst, etc. On the whole there was a slight improvement in quality from this district. Nilgiris and the Wynaad were not represented.

Coffee prices in America. It seems only a very short time ago since the great boom in Mexico as *the* coffee-growing district of the world, but now, alas, the prices of American coffee are so low that Central and South America generally do not smell sweet in the nostrils of the investor. Crops, however large they may be, cannot bring in a profit at the present rates in America. It is not surprising to learn that with Brazil coffee at 18*s.* to 22*s.* per cwt., and retail coffee selling at 4*d.* per lb., that the shares of the much-talked of Dumont Company have fallen from £10 to £2½. No, despite leaf-disease, high exchange and everything else, a good South Indian Coffee Plantation takes a prodigious lot of beating.

China Tea in Thibet. We hope that as soon as the present treaty with China and Thibet expires, the Indian Government will no longer stand on any ceremony in forcing open trade routes to Thibet. In view of the dismemberment of China, it would be little short of ridiculous from repairing to push to the utmost our undoubtedly strong claim on the markets at least of Thibet. In the report of the British Consul at Chung-Ring, writes the *H. and C. Mail,* one of the outposts of observation of Thibetan trade, it is stated that certain Mahomedan merchants have the monopoly of supplying tea, and make annual expeditions to Thibet extending as far north as the Koko Nor. Numbers of the tribesmen also come down to the frontier towns and deal direct with the Chinese merchants; but, as a rule, the Mahomedans act as go-betweens. Tea is by far the most important export to Thibet, the figures for Ta-chien-lu and Sung-pan being about 22,000,000 lbs. per annum. In the look-out for new markets for Indian tea, such trade a as this is worth cultivating.

Low Exchange in China. Although the export trade of China, as a whole, says the *H. & C. Mail,* has benefited by low exchange, there was no apparent effect on the tea trade during 1897. In spite of a further falling off in the shipments of tea, the value of the exports for 1897 exceeded that of 1896 by over 32 million taels. The year 1895 held the record with value of Hk. Tls. 143,293,211, but 1897 has beaten easily and stands at Hk. Tls. 163,501,358, which ne doubles the figures for 1887, although at that time tables included the exports from Formosa. The increa not due to an exceptional demand for a particular art and almost every item, except tea, has shared in expansion. We gather from the consular report that total trade of the port of Ningpo for 1897 fell off to extent of £206,376. Practically the whole of the decr occurred under the head of exports. It is accounted by the opening of Hangchow as a treaty port, and consequent complete diversion of Fychow teas and partial diversion of Pingsuey teas. These two items le a decrease of £372,000, and as the net decline is less t this by £166,401, there was a gain to this extent in o directions. It seems beyond doubt that the days of Ni as a shipper of Anhui teas are over, though Mr. Playfa not quite certain on the point, and is of opinion that "t is less finality about the result than might perhaps inferred from the course of the trade during the year is passed." But at least the figures are against him, the shipments of Pingsueys through Ningpo in 1897 reac 8,210,500lb., against 13,118,667lb. in 1896, and of Fych 1,629,000lb., against 12,050,533lb. The diversion will however, make much difference to Great Britain. The goes to America almost exclusively, and whether i shipped from Ningpo or from Hangchow, it will continu go in British bottoms.

Plague rules on plantations. The following rules have b drawn up by the Ceylon Gov ment for the guidance of the l planters in the event of plague breaking out in South In cooly districts :—

1. Isolate all new arrivals from a plague area in separate l and arrange that they work away from the main body of the e coolies until fully ten days have elapsed since they left the infe area.

2. Look out for illness among them by a particularly ca inspection at muster. The symptoms of plague are: Fever of re commencement, violent headache, severe pain in the back and li and lassitude. The glands of the groin, or in the armpit or neck generally swollen and tender; cough and pains in the chest are quently observed. Delirium comes on early. Death occurs in or three days.

3. Should a suspicious case occur, prevent any of the other co from going to see the sick coolies. Vacate all lines in the immed neighbourhood of the place where the sick cooly is housed, and for the District Medical Officer.

All coolies who have been in the company of the sick are to be under observation, and apart from the main body for a period o days. The sick cooly had better be left and treated in his quarters; the District Medical Officer will arrange for the nur from volunteers among the sick man's friends; a subordinate me officer will be placed on the estate. The Superintendent will see food, fuel, water, stimulants and disinfectants and cloths are at h

4. After the disposal of the case, either by recovery or de (*a*) the best and safest thing to do is to burn the quarters in which patient was. If the quarters are of too permanent a nature for the roof should be removed, the floor should be dug up and remo the walls, door and windows scraped and washed down with merc chlorid solution, after which they should be white washed and a flooring put down. (*b*) Method of disinfecting cloths and beddin Things of small value should be burned. The clothes and bed of patient and attendants should be boiled for an hour in a cal and spread out in the sun for two days. (*c*) Burial of pl victims :—Graves at least six feet deep, well away from water-su or habitations, and the body to be surrounded by quicklime.

rade reports of the 20th ultimo show :—

o, Cinchona and rdamoms.

Cacao.—A better tone prevailed at yesterday's auctions, about 2,707 bags, out of a total of 4,927 bags red, being sold at a general recovery of 1*s.* per cwt. quote—Trinidad, middling to fine red 73*s.* to 76*s.*, grey mixed red 72*s.* 6*d.* to 73*s.*; Guayaquil, Caraquez 75*s.* 7*s.*, Arriba 78*s.* to 85*s.*; Ceylon, middling to fine 70*s.* to Stock 131,982 bags against 135,928 bags last year.

inchona.—The periodical Dutch auctions, the fourth of series, were held in Amsterdam on the 5th. The good ply of 7,086 packages Java bark was catalogued, as pared with 7,923 packages at the preceding sales, and 7 packages in February last.

good demand prevailed, and 5,526 packages sold at dvance of about 25 per cent., the average unit obtained ng 5·25 cents against 4·25 cents at the previous sale; being equal to the last London auctions, or barely per unit.

he quinine contents offered was about 29,000 kilos inst 36,500 kilos last sale, and about 23,000 kilos sold.

he exports of Java bark for the month of April were ,000 Amsterdam lbs., against 560,000 Amsterdam lbs. last r, and for the four months 3,212,000 Amsterdam lbs., inst 1,984,000 Amsterdam lbs. in 1897.

ardamoms.—Of Ceylon a total of 288 cases was offered, with a slow demand only about 120 cases sold at a line of 2*d.* to 3*d.*; chiefly Mysore character, good to fine ght bold pale 3*s.* 6*d.* to 3*s.* 10*d.*, fair 3*s.* 4*d.* to 3*s.* 5*d.*, dium and small 3*s.* 1*d.* to 3*s.* 3*d.*, medium 2*s.* 11*d.* to 3*s.*, all 2*s.* 7*d.* to 2*s.* 11*d.*, brown and split pickings 2*s.* 4*d.*, ds 2*s.* 9*d.* to 3*s.*, ordinary small brown Malabar 2*s.* 3*d.* to 7*d.*; Wild (of five cases offered one sold) at 3*s.* 6*d.*

Of East Indian 35 cases met a good demand and were stly sold, chiefly Mangalore; fine bold bleached 4*s.*, good d 3*s.* 9*d.* to 3*s.* 10*s.*, medium and small 3*s.* 4*d.* to 3*s.* 5*d.*, all 3*s.*, brown pickings 2*s.* 10*d.*; a few lots ordinary small wn Malabar sort 2*s.* 6*d.* to 2*s.* 8*d.*, Seeds 2*s.* 10*d.* to 3*s.* per lb.

---

erplanting of ubber.

The length of time one has to wait before a rubber tree yields any return for the care and cultivation pended on it, which by the way is not very much, makes st planters shy of touching it. Pervaded to an unolesome extent with the idea, sound enough in the main, "one thing at a time," South Indian Planters look with eat distaste on the interplanting of rubber or any other rinsically valuable tree in their tea or coffee. This is a eat pity. The current idea is that if a tree is good for ade, or shelter, timber or fuel, plant it up by all means ongst the existing cultivation. But if a claim is advanced t any income could be derived from the produce of this ade or shelter tree, it is at once looked upon with much spicion. Crops cannot be gathered without manure, and crop-giving trees are planted amongst tea or coffee, they ll injuriously encroach upon the supplies given to the ples. "If it is, you know, why let it be so, and if it be so be it." The very obvious reply to this argument is: nure the crop-giving shade or shelter trees as well as the ple. Planters are, as a very general rule, not able to ord to devote entirely new land to the separate cultivan of new products. Interplanting, therefore, is the only chance they have of testing their value. In Ceylon, it is firmly held that Para, for instance, can be planted in tea at the rate of fifty trees per acre without doing the least harm. Some planters, indeed, declare that 100 trees per acre would be safely planted in certain instances. In some eight or ten years the value of the produce of these 50 or 100 rubber trees would probably largely exceed the returns from the staple itself in its best days. Ceara even, which has now such a wretched reputation, can yield in favourable situations as much as one pound of good rubber per cooly. Para grows in Ceylon up to 500 feet, or even 1,030 feet it is said, but in India—*vide* the Burliar Garden on the Nilgiris—it thrives at about 3,000 feet. By the way, reckoning the acreage by the number of seeds sold, there are about 1,000 acres planted up in para in Ceylon, most of which is under six years' old.

A new coffee-book.

We have received for review quite a curiosity in the shape of a little book on coffee cultivation by one Timma Maistry. It is called "The Coffee Planter's A. B. C., and is most respectfully dedicated to those good sportsmen and gentlemen, the planters of Southern India, by their honour's humble and obedient servant, Timma Maistry." The book is arranged alphabetically, and is capitally got up and printed by the M. E. Publishing House, Madras. Had Tamil and Canarese translations been added, the little work would have been of much use on estates for conductors, writers and maistries. While the book contains nothing new of any importance, "the maistry" shows throughout his little work that he is fully abreast of the latest ideas in planting. His remark on leaf-disease, for instance, is well to the point: "Leaf disease appears, like all fungoid growth, in a greater or less degree, whenever hot sun comes on ground laden with moisture, and disappears when atmospheric air has taken the place of water in the soil. *If, by subsoil drainage, all water could be removed that the soil cannot assimilate, then perhaps leaf-disease would disappear.*', As befits his character of a good all-round man, Timma's hints on the treatment of cooly ailments are simple and practical. When there are a large number of coolies sick, keep them in good spirits, and he sensibly remarks that in such cases a present to make "Sami" often does more good than much medicine. On the whole an excellent little work, full of sound sense and practical advice most useful to young planters learning their A. B. C. at coffee.

Cup and pipe.

Curiously, the subject treated in our article headed "Cup and Pipe,"

COFFEE SHADE TREE.

published last week, writes the *Grocer* of the 14th ult., supplied the principal theme of discussion on the Budget resolutions in the House of Commons on Monday night, when various orators expressed their opinions freely, if without much practical knowledge, concerning the relative merits of tea and tobacco. Truly, as we pointed out, these articles seem to be now acquiring a distinctive importance: statesmen regard them as important factors in the economic and commercial world, and people who do not consume either one or the other or both are thought by some of their fellow-creatures to be deserving of a phrenological examination. On Monday evening, when the House got into Committee of Ways and Means, an opportunity for discussing the budget naturally arose, and Mr. Robertson opened the debate by expressing a decided opinion that it is tea, not tobacco, the Chancellor of the Exchequer should have chosen when he conceded a reduction of taxation. While agreeing generally with the idea thus enunciated, Sir William Harcourt remarked that there are more tea drinkers than tobacco smokers in this country, but he produced no statistics by way of adding force to his rhetoric. Yet the subject is surely worth more than a superficial consideration. It is perhaps not easy to get at the actual facts. All classes of people drink tea, but all classes do not smoke. True, many women are beginning to do so, and boys start earlier than they did in former years, and old men never leave off, as the saying is, while there is a puff in them. All this is good for trade, and we need not make invidious comparisons, or express dogmatic opinions concerning the relative importance of two primary consumable articles. There is reason to believe that the commerce in both will show a satisfactory development in the near future. While, practically speaking, tobacco has no competitor, tea has several, and cocoa, for instance, has of late been well boomed. But tea drinkers are staunch in their devotion; they are not prone to run after what is unfamiliar, if not new, to them. And, after all, there is plenty of room for coffee and cocoa and tea and tobacco, especially if we are to have it better and cheaper. The British workingman may, in this regard, be expected with confidence to do his duty, and contribute nobly—by his smoking, if not by his tea-drinking, enthusiasm—to the Imperial exchequer. Many grocers now supply him with a really wholesome shag at 4*d*. per oz. and under, also with tea of unrivalled cheapness, considering its excellence of quality. This is the good work that we hope to see continued with unabated enterprise and spirit. Slight reductions of duty, either of tea or tobacco, are all very well; but Englishmen are pretty sure to keep their cup filled and their pipe alight even if the Chancellor of the Exchequer does not come to their aid.

London Market.

Coffee.—During April, writes the *Produce Market Reveiw* of May 14th, there was an increase in the European stocks of nearly 6,000 tons, but a decrease in the world's visible supply of 25,000 tons. Probably much of the latter was caused by the enormous deliveries in the United States owing to the scare about an extra duty being imposed, and which amounted to nearly 105,000 tons, or almost double the deliveries in the same month last year. The total stock is now given at 340,010 tons against 256,290 tons last y Although these figures appear enormous, the markets tinue very strong, and at the Dutch sale on Tuesday p were, in nearly all cases, much above the valuations. In market, although the auctions continue excessive, s 24,000 bags being catalogued this week, prices have i cases been well maintained, or are dearer. Only a 2,000 bags of Costa Rica have been offered, and these at an advance of 1*s*. to 2*s*. for fine coloury, while med and common were steady. Larger supplies of Guate have come to hand, and full prices have been paid, espec for all bold parcels. The bulk of the East India has of common quality, and consequently difficult of sale, all the fine lots were sold at extreme rates.

LETTERS TO THE EDITOR.

COOLIES' PAY.

R,—Whilst *Planting Opinion* reports coast coolies "flocking Coorg at As. 4 pay," I hear of estates paying As. 6. Is this Coorg)? At any rate, how about the combination supposed nd that should) exist amongst planters?

th May, 1898. S. C. P.

YOUNG PLANTS DYING.

R,—May not this be the cause of young plants dying after arly showers, viz., before the fall of the early showers the nd is dry, parched, and as hot as a kiln, not a drop of rain ng fallen for perhaps three or four months. Rain coming n on earth in this state would, I should think, cause a great ınt of evaporation; hence heat. In fact, your plant gets a of steam bath, or rather the roots do. Perhaps, this boiling eders *doesn't* quite agree with young plants?

n a great many estates, where the surface soil is not deeper 6 to 10 inches, you see pits dug to the depth of 18 inches, bringing a great part of the subsoil to the surface. Is it not stake to spread your subsoil—probably a stiff clay—over your ace soil? A mistake in more than one sense! If 18-inch pits required, by all means have them, but directly they have been put the soil back as you found it. Subsoil where subsoil ld be, and the surface soil on top. Not as many men do, scrape all the good soil into the pits and leave the inferior on the surface; by so doing, I have no doubt the plants do well for the first few years. But does it pay in the long ? I am, of course, referring to coffee.

K. D. H.

GENERAL ARTICLES.

THE U.P.A.S.I. SECTION.

[UNDER THE CONTROL OF THE SECRETARY, U.P.A.S.I.]

HE following is Mr. Howard O. Newport's third rative report of his quest of Lady-birds, dated Gatton, eensland, 14th May, 1898:—

THE SECRETARY,
UNITED PLANTERS' ASSOCIATION OF SOUTHERN INDIA,
Madras.

EAR SIR,—I regret I was not able to write last mail as I intended o. I was away from headquarters and returned too late to catch English mail.

ince I last wrote I have had some trouble with the ice chest. und an ordinary ice chest would not bring the temperature low ugh to suspend animation in the Lady-birds. This had to be e, of course.

Ir. Tryon had had no experience of this part of the business, and ny perplexity I called upon the Engineer in charge of the Rail- Cold Storage Works. He, I found quite by chance, had had e practical experience in this very line, having sent insects from S. W. to California. He had, he said, put the insects into a perature below freezing point. He gave me a plan of a brine st that would bring and keep the temperature low enough to p the insects dormant. This I took to Mr. Tryon and with his roval had constructed.

n fact, the Agricultural Department had it done for me in their workshop. The construction of this case delayed my collecting work for some ten days or more, but it was absolutely necessary. Since it has been completed I have been collecting steadily and have been successful in getting a good number of insects. I am making arrangements now to return to India by the O. S. N. Co.'s steamer leaving Sydney on the 28th instant. To catch this I leave Brisbane by boat on the 25th instant, and should arrive at Colombo on the 17th or 18th June.

Before leaving I will, of course, submit my insects to Mr. Tryon's inspection. Should he advise me to wait for another fortnight and collect more of any one kind of insect, I will do so and leave by the boat of the 11th June, but I do not anticipate his suggesting this.

I beg to submit my accounts for the month of April.

I have to the end of April drawn £60 from the letter of credit I hold for £160, and expect to have to draw some £30 or £35 more before my arrival in India.

ARE NITROGENOUS MANURES NEEDED?

OUR readers must be now fairly familiar with the subject of soil-bacteria, and the highly important part they play in agriculture, in converting inert nitrogen into nitrates. A Mr. Baur, whose letters to the Ceylon papers we have frequently noticed, now makes the final step by declaring that, in his opinion, no nitrogenous manures are required at all. This is, of course, with special reference to tea, and considering the more nitrogenous nature of a tea crop, it must—theoretically be it observed!—hold good with coffee. To prevent any misconception, we may mention here that Mr. Baur's extreme theories are by no means above suspicion, and that we hold them only to be partially true, at all events under the present conditions of plantation-working. According to one of the most noted French agricultural scientists of the day, the average loss of nitrates as shown by drainage waters is as much as 88 lbs. of nitrogen per acre per annum. This is the average of many soils, uncultivated and unmanured. These 88 lbs. were lost mostly in autumn, 37 lbs., the quantities for winter, spring and summer being 11, 16 and 24 lbs. respectively. Some of the soils were well-loosened and exposed to the air, with the result that the drainage waters proved the formation of 195 lbs. of nitrogen per acre the next year, falling to 71 and 65 lbs. the two succeeding years. This demonstrates the enormous value of loosening and stirring the soil.

Granted that all this nitrogen is converted into nitrates in the soil, Mr. Baur is a great deal too hasty in jumping at the conclusion that there is no loss of these nitrates in

land under such cultivation as tea. When even land under such crops as grass, wheat, and clover show a loss of nitrates under the gentle European rains, it is clear that our coffee and tea lands, especially if steep, must suffer an even greater loss. On the other hand, it may well be that in moist, warm districts, nitrates are formed in greater quantity than in Europe, and so be better able to afford their greater loss.

On the assumption that more nitrates are provided in the soil than the largest crops of tea can take up, Mr. Baur argues that small yields must be due to the lack of other constituents, in other words to a want of soluble phosphates and potash. If these minerals were supplied, he holds that the increased crops would at once demonstrate the truth of his contentions. *Pari passu*, the undoubted effect of soluble nitrogen in the form of nitrates or poonac prove just as conclusively that the soil-formed nitrates are not retained in sufficient abundance for the purpose of producing the largest crops. There is no escape from this quandary, except by going a little deeper into the elements of agriculture. Make the soil more retentive, better able to hold up the nitrates, and your store alike of soluble nitrogen and of soluble minerals will increase in direct proportion.

Mr. Baur has done good service in attracting attention to the subject of minimising the planters' manure bill, but he does not go far enough. There is no doubt that almost every soil contains plant-food, in its inert state, in enormous quantities. The great task is to render these stores soluble. Deep and thorough cultivation, and a really intelligent system of drainage, would effect an enormous saving in manure. More than that, manure applied to thoroughly worked up soil is practically all utilised. At present for every anna's worth of poonac or other manure taken up by the plant, fifteen annas are wasted.

Some day another Mr. Nelson will arise, and demonstrate as successfully as that gentleman a system of cultivation without manure even more perfect and valuable than the one based on the now widely-known *Erythrina lithosperma*.

SOURCES OF COMMERCIAL INDIA-RUBBER.

BY DR. MORRIS, C.M.G.

SINCE the days when Le Condamine first described the rubber tree of Brazil and Don José, King of Portugal, in 1755 sent several pairs of his royal boots to Para in order that they might be covered with the waterproof 'gum-elastic,' the use of India-rubber has enormously increased. Besides the demand in almost every department of arts and manufactures, the rapid development of cycling and of the use of rubber tyres for carriage wheels has added to the increased consumption of this interesting article. The quantity of raw caoutchouc imported into the United Kingdom in 1830 was only 23 tons. Even in the year of the accession of our Queen it was only about 200 tons. Last year it had increased to 20,000 tons—exactly a hundred fold.

The present value of the imports is about five millions sterling. The total trade is probably not less than ten millions sterling. More than one-third of the imports is now received from British possessions. In 1888 only about one-fifth was so received. It is estimated that the world's consumption of rubber is 60,000 tons, of the value of 14 millions sterling. This stupendous quantity of raw material is laboriously extracted from the milky juice of trees and shrubs belonging to three natural orders, viz. the Spurges (*Euphorbiaceæ*) the Nettles (*Urtienceæ*) and the Dogbanes (*Apocynaceæ*). These plants are distributed over nearly every part of the tropical zone—none are found in the temperate zones—the most important being found in the vast basin of the Amazon, an area almost as large as that of the Continent of Europe; others are found on the East and West C of Africa, in Assam and the Malay Archipelago.

Hitherto the preparation of India-rubber has depended upo crude hereditary art of a semi-savage people, the rubber-hunters explore the depths of tropical forests and obtain the rubber m the sacrifice of millions of trees, which, owing to the reckles with which they have been treated, are yearly decreasing.

The result is that many localities where rubber was once al antly obtained have almost ceased to produce it. New sourc supply have, it is true, been found in West Africa, especial Lagos, the Congo State and Portuguese South-West Africa. here also the work of destruction is rapidly going on. The colle have to go farther and farther into the interior, and the co transit is thereby greatly increased. An account was given b lecturer of an important discovery whereby the rubber coul extracted from the milk in a perfectly pure state. This is a m nical contrivance on the principle of a cream separator. This likely to prove of great value in the preparation of Central Ame and some West African rubbers where the milk flows in an app able quantity and is capable of being brought in by the colle It would be indispensable on regular plantations of rubber-t By such means the process of preparing the rubber could be under scientific control, and all injurious substances such as pro and all dirt and chips excluded. The value of the rubber so pared has been shown to be increased fully 25 per cent.

The rubber-trees of Brazil were then exhaustively described gether with the distribution of the various species yielding the rubber of commerce. The exports from Para in 1897, inclu rubber received from Bolivia, Peru and Venezuela amounted to 2 tons. Of this amount, 51 per cent. was shipped to the U States and 38 per cent. to the United Kingdom, leaving only a 11 per cent. or 2,500 tons for all other countries.

The price of Para rubber, which regulates the prices of all sorts, has been steadily increasing since 1894, when it was 2*s.* per pound; in 1895 it rose to 3*s.* 2*d*; in 1896 to 3*s.* 4*d*; in 1897 t 6½*d*; while the average price for the first three months of 1898 3*s.* 9½*d*. At the last sales on the 15th instant, it was 3*s.* 11*d* pound. It was, however, pointed out that these prices were b what they were in 1882 and 1883, when fine Para fetched 4*s.* 4*d* pound.—*Observer.*

CEYLON ASSOCIATION CURRENCY MEMORIAL

THE following is a copy of the memorial against the proposa the Government of India sent by the Ceylon Association in Lo to the Rt. Hon. Jos. Chamberlain:—

CEYLON ASSOCIATION IN LONDON,
61 and 62, GRACE-CHURCH STREET, E.
May, 189

Sir,—In view of the serious depression in trade in Ceylon ca at the present time by the forced contraction of the currency, of the losses in which the Ceylon producers are involved by th titious value given to the rupee, the Ceylon Association in Lo desires to place its views before you in such a manner as to en that the interests of the Colony may be fully considered be decision is come to by the Government on the policy to be pur with regard to the Indian Currency.

2. Ceylon has not, like India, several leading staple prod How dependent the Colony has been on her one staple product, only in the matter of her general prosperity, but also of her pu revenue, may be shown in a few words. In 1877, when coffee was flourishing, the revenue amounted to R17,020,190; with the failu coffee the revenue fell in 1882 to R11,161,570. From 1882 to present time the great tea industry has exhibited a steady and r development, and the revenue has in like manner increased yea year till in 1897 it amounted to about R23,200,000.

3. As it may be said, without exaggeration, that tea saved Colony, so also the future of the industry, from whatever ca would most assuredly bring on the Government the gravest finan trouble, on tea estate proprietors the loss of some £15,000,000 ster and on a large number of the native population wide-spread ruin

4. These are the considerations, admitted in Ceylon as valid by officials and unofficials, that cause the Association to view the utmost alarm the policy of the Indian Government with regar the Currency.

5. From the date of the introduction of tea, till the effects of cessation of coinage in India stayed the steady downward mover

change, the tea industry grew and prospered greatly. Good ts were made, though the gold price of the produce was con-ly falling, and large areas of land were brought under cultiva-

The establishment of the 1*s.* 4*d.* rupee has at a stroke seriously iled profits and raised such alarm for the future as to check any ier extensions.

The cost of the present crop of Ceylon tea, estimated at 00,000 lbs., will be about R36,000,000, so that every additional y in the exchange value of the rupee adds £150,000 to the gold of the crop.

China, meanwhile, retains her silver currency; and as the *l.* rupee is nearly 7*d.* above its intrinsic silver value, it is clear that ual gold prices, Ceylon will, in competition with China, stand at advantage, on this year's crop alone, of a million pounds sterling.

The Ceylon and Indian tea industries, when competing on fair even terms on a silver currency, were able without difficulty to e China tea out of the home market.

Extended cultivation both in India and Ceylon then made it ssary to find new markets abroad for the increasing weight of uce; and large sums of money have been and are being spent in avouring to introduce British-grown teas into some of these kets, notably North America and Russia. Some measures of ess had been achieved, but the markets being already held by a and Japan, it is manifest that under the circumstances stated e the difficulties of making further progress have been enorm-y increased.

. The competition of China will be all the more formidable in future inasmuch as powerful efforts are now being made by cap-sts to establish in various parts of China Tea Factories equip-with the latest machinery; and tea thus prepared, produced by ur paid in cheap silver, will be able to undersell the more costly of India and Ceylon in every neutral market.

. Advocates of the closing of the Indian Mints and of the blishment of the fixed 1*s.* 4*d.* rupee have held the opinion that idence would thereby be restored and that capital would flow y into India. In the matter of tea this currency policy is having, we venture to think, will continue to have, probably in an easing degree, the very reverse effect.

. The present hopeless position of the sugar-growing Colonies is rning of the disasters that await producing industries subject to nty-fed competition. This Association foresees the possibility of ke fate overtaking British-grown tea should the value of the ee be maintained so much above its value in the standard of the ntries competing on a silver basis.

. The position of the Colony would be, in that base, it is feared, ne respect even worse than it was on the failure of coffee, inas-h as there will be no other product available to take the place ea.

. Special stress has been laid on the effects of the Currency posals of the Indian Government on the tea industry as being most important of the industries of Ceylon; but the consequent ease in the gold cost of production will affect equally every luctive industry in the Island. All exported produce that seeks arket open to competition with the produce of silver-using coun-s will further suffer from the fall in price that must result.

. Two diagrams are sent herewith; the one showing the rates Exchange and the selling price of Ceylon tea in sterling and ees respectively, the other the annual exports of tea from Ceylon n 1882 to 1897. I have the honour to be, Sir, Your obedient vant (to be signed on behalf of the Association).

To the Right Honourable J. Chamberlain, M.P., Her Majesty's Secretary of State for the Colonies, Downing Street, S.W.

THE FISCAL HISTORY OF TEA.

(From the Customs Tariffs Blue-Book.)

HE first mention of tea in the statutes is in the Acts 12, Charles c. 23 and 24 (1660). By the latter Act, certain burdens upon the ject arising from courts of wards and liveries, and tenures by ghts' service and otherwise, were abolished, and in order to re-e the revennes which had been received therefrom a number xcise duties were granted to the king, among which was the owing:—

or every gallon of chocolate, sherbet, and tea made and sold, to aid by the maker thereof 8*d.* and a like amount was granted as ty of excise, by the other Act quoted.

But experience showed that this collection of duty upon the liquor of tea and chocolate (as well as upon that of coffee which had also been enacted by the before-mentioned Acts) was so burdensome and expensive to the Crown, as well as unequal in its bearing upon the dealers, that the provision in question was repealed and a net duty of 5*s.* per lb. imposed in 1698 by 1 William and Mary, sess. 2, c. 6.

Tea is not even mentioned by name in the Book of Rates issued with the great Customs Act of Tonnage and Poundage of 1660, but if imported at that date*—and there can be little doubt from the enactment noticed in the first paragraph that it then formed an article of importation—it was liable to the payment of the general *ad valorem* duty of 5 per cent. which was due on all goods not specifically rated. This customs duty was in addition to the excise duty on the liquor of tea already mentioned. Tea, however, must very soon have become an article of sufficient commercial importance to command the particular attention of Parliament, for another Act, passed in 1695, made it liable to 1*s.* per lb. duty if lawfully imported, that is, in ships of the East India Company and from the place of its growth, and 2*s.* 6*d.* per lb. if otherwise imported. By 3 and 4 Anne, c. 4, these duties were doubled in 1704; and again in 1712, 10 Anne, c. 26, 2*s.* per lb. was added in the case of tea imported from the East India Company territories, and 5*s.* per lb. if imported from elsewhere.

In 1721 it was found necessary to prohibit the importation of tea from the continent of Europe, owing to the fact that a trade had sprung up which militated against the interest of the East India Company, who alone had the right to import tea into these islands. In 1724 the excise duties on tea were consolidated into a single inland rate of 4*s.* per lb., but in 1745 this high rate was altered to 1*s.* per lb. and 25 per cent. *ad valorem*, calculated on the prices realised at the East India Company's sales; this duty being over and above the import duties. The reason for this charge was that the revenue collected at the sales in London and paid over direct to the Crown by the East India Company was less liable to be evaded than such as was collected from a number of traders by the excise authorities. The East India Company in return for their privilege were held responsible for keeping the London market supplied with a sufficient quantity of tea, in default of which the Treasury were empowered to grant licences to other persons or bodies corporate to import tea from Europe. In 1773 the reserve amount which the Company should keep in warehouse was fixed at 10 million lbs.

In 1777 it was found that the high duties, added to the prime cost of tea, had made the article so expensive, that great incentives existed to adulterate it with dried leaves of sloe, ash, and elder, and with liquorice and the re-dried leaves of used tea, and a penalty was enacted of 5*l.* for every pound of such adulterants sold or found in any person's possession. But the smuggling and evasion of duty went on without much abatement until 1784, when it was determined by Parliament to collect the whole of the duty on tea by the agency of the East India Company. The existing duties were therefore repealed, and in lieu thereof a single modified rate of 12½ per cent. on the value of the teas sold by the Company was enacted. They were to hold not less than four sales every year, and to put up at least 5 million lbs. at the first sale and 2¼ million lbs. at the second, and in order to prevent abuse by the Company of the monopoly thus accorded to them, it was further laid down that the upset prices at which the teas should be put up should not exceed for the first four sales—

For Bohea	...	1*s.* 7*d.*	per lb.
For Congou	...	2*s.* 5*d.*	„
For Souchong and Singlo	...	3*s.* 3*d.*	„
For Hyson	...	4*s.* 11*d.*	„

The teas to be sold without reserve. The Company were further to keep at least one year's supply in stock, and afterwards to put the tea up to auction at a commencing price not exceeding its prime cost and charges for freight and insurance. This Act was generally known as the Commutation Act.

By the 18th Geo. III., c. 26, the grant of drawback of duty upon teas exported was made to cease altogether, owing to the constant frauds which were practised. This enactment pressed heavily upon Ireland, because all tea was imported in London, and by the 7th of Geo. III., c. 56, and some other laws, a portion of the import duty

* The following entries occur in Papys' Diary:—"Sept. 28, 1660. I did send for a cup of tea (a China drink) of which I never had drink before and went away (the King and the Princesse coming up the river this afternoon as we were at our pay)." "June 28, 1667. Home, and there find my wife making of tea; a drink which Mr. Pelling, the Potticary, tells her is good for her cold and defluxions."

was returned upon teas sent to Ireland—generally three-fifths of the full duty. Subsequently, in 1777, Parliament granted, upon exportation of tea to that country, a drawback of the full customs duty which had been paid on importation. (17 Geo. III., c. 27.)

In 1795 an addition of 7½ per cent. was made to the excise *ad valorem* duty to be calculated on the prices realised at the sales, and in the next year a further 10 per cent. was added in the case of teas of a higher value.

Further additions continued to be made to the duty, and at the close of the eighteenth century the average price of Congou tea at the sales was rather over 3*s.* a pound, exclusive of the duty, which amounted to the not excessive rate, on an average, 1*s.* 2½*d.*, or, taking price and duty together, 4*s.* 2½*d.* per lb. This, of course, was independent of the retailer's profit, which doubtless added considerably to the price before the article reached the consumer.

During the war with France, the duty rose considerably, and in 1811 the average rate was 3*s.* 4*d.* per lb., the average wholesale price in bond being also just about the same, making the total wholesale price inclusive of the duty as high as 6*s.* 1*d.* a pound.

(*To be continued.*)

GOVERNMENT GARDENS IN THE N.-W. P.

THE Government of the North-Western Provinces and Oudh maintains four public gardens and one fruit orchard, viz., the Botanical Gardens at Saharanpur, the Horticultural Gardens at Lucknow, the Taj Gardens at Agra, the Khushru Garden and Alfred Park at Allahabad, and the Muktasar Orchard in Kumaon. Reports on these are submitted by the Superintendents in charge, but there are a few other gardens, such as the Cantonment Garden at Agra, the Memorial Garden at Cawnpore, and perhaps a few others, about which, however, we seldom hear; at any rate, we do not suppose any reports are submitted on the working of these. The two first named are entirely under the control of the local Department of Land Records and Agriculture; the third is under control of the Commissioner of Kumaon, while those at Agra and Allahabad are under the local authorities, though the Director of Agriculture is associated in their management, and is the channel for the submission of their annual reports; but his connection with them is almost entirely of a consulative nature. The first three gardens carry on work of agricultural interest, while the last two are maintained for ornamental purposes. We are indebted for the foregoing information to the report of the Director of Agriculture on the operations of his department for the year ending 30th September, 1897.

The Taj Gardens could scarcely be made to serve a utilitarian purpose, but it seems to us that the three other gardens under the control of the Superintendent of the Taj Gardens, viz., the Rambagh, the Itmad-ud-Dowlah and Secundra, could be converted into experimental gardens; the question of funds, however, would doubtless have to be considered. The Khushru Bagh at Allahabad has so far served no useful purpose whatever, but were a competent Superintendent appointed, who took some interest in his work, there is no reason why experimental cultivation could not be carried on; the Alfred Park is purely ornamental.

The Saharanpur Garden seems to have done extremely well last year, notwithstanding the deficiency of rainfall, which told adversely on the orchard; though vegetables did well, and the issue of fruit trees, grafts, seeds of vegetables and flowering annuals and cuttings of ornamental shrubs was larger than in the previous year. In its scientific section the garden did good work for the Reporter on Economic Products, while experiments were conducted with food and fodder products and other articles of economic value. What these were is not stated in the report, but possibly when we receive the report on the garden we shall know. Sisal hemp, the Director tells us, "was successfully naturalised; considerable quantities of rhea were grown, and varieties of sugarcane, formerly strange to Saharanpur, were introduced to the neighbouring zemindar much appreciated." The year's working resulted in a pro Rs 2,321. The most interesting feature of the work at garden was the experiment in the preservation of fruits vegetables by evaporation. Reference was made to this i issue of 14th October, 1897. Mr. Gollan, the Superinten has been experimenting with Ryder's Evaporator. We ar told that a considerable quantity of fruit and vegetables been dried by this machine, but Mr. Gollan considers h yet to reduce the cost of drying before the products cou successfully put on the market. "Samples of the pr have," says the Director, "since the year closed been rec at this office, and it is proposed to send them to a few le mercantile firms to report." Experiments on a smaller have been made by the Assistant Director at Cawnpore, " a cheap German Evaporator, which was recommended b Voelcker in his paper on the fruit-drying industry of Gerr published in the Journal of the Royal Agricultural Socie England in 1896." This cheap machine, "made in Germ does not seem to have been a success, as the process of d with it is described as "tedious," and the wooden trays "re constant watching," as "the heat has to be regulated great care, in order to prevent the fruits from being overhea The Director adds naively: "Further trials will be made, ever, as there is still much to be learned about the art."

Like Saharanpur, the Lucknow Gardens suffered fr deficient rainfall. The Arabian date palm again gave un factory results, which should interest Dr. Bonavia. We the detailed report before dealing with the work of this ga The facts given by the Director in regard to the working Muktasar Orchard in Kumaon are altogether too meag base any criticism upon. We await the detailed report o orchard also.—*Indian Government.*

WASTE OF FRUIT SEEDS.

IF we come to consider the enormous quantity of seed t daily consigned to the dust-bins of our larger cities and sta and the vast area of waste lands that must yet remain un vated for many years to come, says a writer in an exchan seems a pity that the more robust trees should not be rais our reserved and less accessible forests and left to Natu develop. Mangoes are more than usually abundant this and the same may be said of lichees and some other fruits goes without saying that the outer slopes of our moun abutting on the plains, that have been denuded of their ti by the pernicious system of *jhuming*, would be all the bett being brought under new growth of the more satisfying f while at the same time, as the timber attained maturity, barren unprofitable stretches of country would become cisterns as they were before the ruthless hillmen converted into bare, dry, rocky deserts. Of course, we could not, at expect these places to become the dense forests they wer most of the soil has been washed from them, so that the i steps for rehabilitation would have to be confined to such cre as have been unexposed to the rush of water and in wh certain proportion of soil remains. We cannot induce *jhumer*, who only lives for the present, to adopt a more civ method of agriculture, but the forest authorities might insist upon his putting in a certain amount of seed the last s of his occupation of the land; mango, jack, and such timber as jarool, julna, simul and others would not in the least int with his crops, and though after the place had been aband there might be some danger from grass fires, an arrange could be come to rendering it incumbent on the former occu to cut down the grass and brushwood about the beginni December, as the heavy dews and Christmas rains would re it to rotten vegetable matter, less liable to take fire than i

row unchecked until March, when these fires usually take
e. Our trunk roads, bunds of tanks, railway embankments
other similiar sites would take no harm if laid down with
tations of papaya and other light fruit trees, the roots of
h do not ramify into, or split the soil, and which, if thrown
ss the rails by storms, would not impede the traffic. It is
to witness the waste of the seeds of our fruits, especially
n we consider the health-giving properties all possess, and
gh disapproving of appealing to Government for assistance
l and every occasion where the benefit of the general commu-
is concerned, I think in this instance the aid of district officers
ld be invoked and jail labour employed in carrying out the
e suggestion. Of course, the selection of seeds must not be
scriminate, only those of the very best quality being chosen,
rom the general ignorance of the Indian peasant on all
ils of cultivation, aboriculture especially, the average fruit
ght into our markets is of decidedly inferior quality.
da or Bombay mangoes, China or Malay lichees are best
ed to Upper Assam, South Sylhet and certain parts of
nar, while the seeds of papaya and the better class of
tains would thrive in the moister climate of North Sylhet
along the foot of the Bhutan mountains. In fact, the
aya as well as all the citrons of the Khasia Terai are not to
qualled in any part of the world, and it is from this district
I recommend seeds of these latter should be procured.
it must be remembered that citrons will not attain per-
ion without the aid of lime; it is also as well to mention
the famous orange groves, usually, though erroneously,
wn as the Sylhet ones, are subjected to an annual down-
of some 380 inches, besides being occasionally entirely
nerged.—W.

CACAO DISEASE INVESTIGATION.

INTERIM REPORT BY J. B. CARRUTHERS.

(*Concluded from page* 267.)

HE experiments with regard to the canker in the stem were more
orate. I selected a number of trees 5—7 years old in different
s of the estate, and chiefly in new clearings of both Forastero
Red varieties, all of which to all appearances were entirely free
n disease, and whose tissues showed no sign of mycelium when
mined under microscope. These I proceeded to treat by inocula-
. The method of inoculation adopted was to make a slanting
so as to expose all the different tissues from the cortex to the old
d, and to insert by means of a paint brush the spores, or in the
of those inoculated with diseased bark to insert a thin slice, and
e cuts were then bound up firmly.

used some 30 trees and treated them in the following way :—

t.—13 trees inoculated with the smaller spores, which I have
viously described.

nd.—6 with the secondary septate spores.

rd.—10 with diseased bark containing mycelium.

n each of these treatments both Forastero and Red Cacao were
d, and in one or two cases suckers were also treated.

ince these experiments were being carried on in an extremely dry
on, and the atmosphere was very different from the rainy times,
en the disease undoubtedly spreads, I wished to imitate as far
possible the conditions which are to be found in the wet seasons,
so place these inoculated parts under the most favourable condi-
s for the germination of the fungi. I therefore kept them damp
means of moist paddy straw, which was tied on to the tree, and
vetted daily, after I had examined the case; in cases where the
had access and was likely to dry this up rapidly, I placed shades
r the part treated.

hese were carefully watched for any sign of the disease, and, as
be supposed, those inoculated with the diseased bark contain-
the mycelium were the first to show any sign, and first
all a Red Cacao produced the sporophores of the fungus
r nine days, and all the other Red Cacao followed suit
acquired the disease with the exception of one tree in which the
straw treatment had been intentionally omitted. In the case of
three Forastero trees treated with diseased bark, one has, up to
the time of writing, taken the disease and the other two are in a suspicious condition.

In the eleven cases treated with the smaller spores, six were Forastero and seven Red Cacao. Three of the Red have developed symptoms after more than fifteen days, and one of the Forastero.

The cases treated with secondary spores (those described as crescent shaped and septate) have none of them at present shown any sign of the disease.

The external signs of the canker are being carefully observed and recorded, and permanent microscopic preparations made of its various stages, as well as many other observations and drawings which at present have no significance, but which with the progress of the investigation may be useful in throwing light on many questions of interest.

Usually the first external sign of disease is a moist spot on the tree with often a drop of claret or brown-coloured liquid exuding from it. When this runs over the surface of the bark, it gives it a rusted appearance—later the sporophores burst through the bark at different places, being at first white in colour and changing gradually to a red or brown—the size of these sporophores varies from that of a pin's head to almost the size of a pea, and the shape is as a rule round or oval. In the cases on older bark they are forced through the cracks already existing in the bark, and thus they appear more or less in vertical lines. The tissue is at first of a neutral tint, and later becomes brown and finally dark claret coloured. In most of the cases observed the fungus seems to spread more rapidly round the tree than vertically, but the rapidity of growth varies in the different trees, and no opinion can be as yet formed as to this most important matter.

The three trees not kept moist by means of wet paddy straw have none of them acquired the disease, and this during the recent dry weather is as expected. In regard to the trees which have developed spmptoms of the canker, those inoculated with tissue containing the mycelium would not usually be sooner affected than those treated with spores—just as transplanting is quicker than growing from seed. No doubt much valuable knowledge as to means of prevention or cure will be gained from these trees as well as that for which the experiments were instituted, the observation of the different stages of growth of the fungus.

With regard to the future work, the main questions still to be solved by observation and experiment are the following :—The conditions of heat or dryness which will prove fatal to spores. The time—if any special time exists—for the formation of each kind of spore. The means by which the spores gain entrance into the tissues of the stem, whether they first germinate outside the bark or get in by a wound—and in this connection it must be remembered that the spores being of such a minute character need no appreciable wound. To give some idea of their size—in the case of the small spores first mentioned, more than 50 million would be required to cover with one layer a square half inch, which is about the same superficial area as a ten cent piece.

Another extremely important question on which I am making many observations and experiments is the question of the effect of heat and dry atmosphere on the cankered spots of the tree. I have observed in many cases that the characteristic moist claret-coloured tissue dries up, and on cutting has all the appearance of dead wood. In these cases the mycelium is not to be found in a microscopic examination, and if present at all must be in a dried up and probably entirely lifeless condition. The conditions which bring this about and whether the tree subsequently forms new and healthy tissue at the spot are problems which must be discovered. The question of the effect of cutting out portions of the canker, how far in bad cases it is practicable, and what measures should be taken, if any, for protection of the wound is of great practical importance, and will be experimented on at different estates where the conditions vary.

So far as these investigations have gone—and they are of course in an incomplete state—though certain facts have been established, yet it is too soon to talk of possible preventives or cures—and a cure in these cases of parasitic fungi in permanent parts of a plant is always a more difficult problem to deal with than a prevention.

Until a complete knowledge of the enemy you are dealing with has been gained, all experiments in these directions must be empiric and to a certain extent unsatisfactory, yet it may be well to state the facts already learnt and what precautions they teach us to take. In the case of the canker the malady is due to a specific disease caused by a fungus which inhabits the growing tissues of the stem,

and in the pods such a disease caused by a different fungus also exists.

As I have previously observed, the conditions necessary for the growth of fungi are moisture and heat—the heat in Ceylon is always sufficient, but the moisture can be to a certain extent controlled. During the rainy seasons the atmosphere continues moist where the sun is not shining, but when the sun is up, unless the place is too densely shaded, the atmosphere must speedily become too dry for the germination of spores. It is thus most important that a minimum of shade should be employed—the amount of shade necessary for the profitable cultivation of cacao—to prevent attacks of Helopeltis, to protect from wind, and other reasons are questions which experience in planting shows, and which I will not presume to advise, but from my point of view, as far as the canker is concerned, this shade should be reduced as far as possible.

It also follows from the observation already made that a great risk is run by allowing any bark on which the sporophores or spore-bearing portions are present to remain on the trees, and all this should be destroyed by burning, which is the only absolutely effectual means of ensuring destruction of fungi. This also applies in the case of the pod disease, which should be stamped out if care is taken to destroy the husk of every pod as soon as it is observed to be attacked.

Any report until the life history of the fungus has been entirely observed, and the rate of growth of its different stages determined is, to a certain extent, unsatisfactory, and therefore it is of great importance that those interested in the cacao disease should remember that this is only a portion of the result of an investigation carried on as far as is possible on scientific principles, and that hasty conclusions on data more or less incomplete are not likely to materially help in the eventual elucidation of the questions of prevention and cure.

J. B. CARRUTHERS.

March, 1898.

ADDITIONAL NOTE AS TO EXPERIMENTS.

On many cacao estates the superintendents reading this report may be inclined to themselves help on this investigation, and, therefore, a few remarks as to experimental work which they could do may be of use.

The most important point in carrying out such experiments is exactitude in recording what has been done, and after observation what the effects are at regular and frequent intervals. No doubt much useful information will be gained if the data are carefully recorded, and it is hardly necessary to specify the exact knowledge to be got by each experiment. I will therefore briefly state one or two examples of how to treat such cases.

1. To cut out carefully the whole of a cankered part, taking care that no discoloured tissue remains behind and leave the wound so made to the drying influence of the air, and also, if possible, to take a stem which gets direct sunlight on it. (Neither of these experiments of course, could be expected to succeed in thick shade.)
2. To cut as in No. 1 and treat the wound with tar.
3. To cut as No. 1 and treat with Bordeaux mixture as recommended by Mr. Willis in his report, viz.:—

Copper Sulphate (Blue stone)	6 lb.
Quick Lime	4 ,,
Water	45 gals.

4. To scrape the cankered parts without entirely cutting them out and apply the mixture.
5. To cut out strips about one inch apart and about one inch in breadth in the cankered parts and treat as before.

In all the cases of using copper sulphate as a fungicide, its liability to being washed off is a difficulty, and experiments with regard to modifying this are important. They may, however, be left to the ingenuity of the individual experimenter if it is always remembered that the basis of the application must be the blue stone. In France molasses have been used, and this mixture resists the action of the rain remarkably well, using only one-tenth of the weight of molasses to that of copper sulphate. Dextrine linseed oil and other substances have been used, but what is of course best is to use a cheap locally produced substance which can be readily obtained.

If these or any of these suggested experiments are carried out, I shall be obliged if those superintending them will communicate with me, so that I may take advantage of the information gained and also, if possible, inspect the trees myself.

J. B. C.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (May 20, 1898) sa

Public Sales continue on a large scale, and the heavy supplies br forward met a good demand at about previous values.

Nearly 6,300 bags East India were catalogued and the greater par sisting of small lots, sold steadily; whilst five Home Trade marks we keenly competed for at very full prices.

Large quantities of Central American kinds were offered and mostly disposed of at about unchanged rates for all descriptions.

The Terme Market has been quiet and quotations show little change since our last.

Messrs. Wm. Jas. and Hy. Thompson's Report of the Colonial Mark the Week ending May 18th, 1898, says:—Bank rate 4%. Bombay Exc closes at 1s. 4 1/16d. Brazil Exchange 5 3/16d. Rupee paper 3½% 62. 26 7/16d. per oz.

A steady demand continues to prevail at auctions prices, at the being fully up to last week's for all kinds, the market continue supplied. Brazil markets are unchanged.

Daily receipts averaged 8,700 bags in Rio and 6,800 bags in Santo

Futures have been quiet, and close 6d to 9d per cwt. lower, viz.:— average Santos in Havre, September delivery, fcs. 36, in Hamburg and No. 7 low ordinary Rio in New York $5.70.

To-day's London official quotations are:—

	May	July	Sept.	Dec., '98.	Mar.	May
SANTOS ...	28/9	29/	29/9	30/3	30/6	30

We quote:—

UBSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly t Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including age. Single Copies, Eight Annas.

DVERTISEMENTS.—From the 1st October, 1897, the charge for advertisements will be: 4 as. per line for the first, 3 as. for the second, 2 as. for the third and succeeding insertions. Five-line advertisements Subscribers will be inserted for three issues for one rupee; non-Subers will be charged two rupees.

OMESTIC OCCURRENCE.—The fee for inserting a domestic rrence will be *One Rupee* for each insertion, payable in advance.

.B.—Remittances should be sent to the Manager, "Planting Opinion," 2, Second Line Beach, Madras.

IMPORTANT NOTICE.

The Business Offices of this paper having now been oved to Madras, all remittances should be made pay- to the Manager of *Planting Opinion*, 11 and 12, ond Line Beach, Madras, who will also attend to all ertisements, &c.

Letters to the Editor should be addressed to Coonoor, usual.

SEASON REPORTS.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 24th June, 1898.

Season Reports should be sent to the Printers, Messrs. ADDISON & Co., direct, and not to *Planting Opinion* Office.

Nilgiris. KULLAKAMBY, 16*th June*.—*Weather.*—S.-W. Monsoon still blowing strongly and damp drizzly weather continues. *Crops.*—Berries swelling. *General Health.*—Fever still very prevalent, and labour laid up to a great extent.

Coorg. POLLIBETTA, 15*th June*.—*Weather.*—Monsoon set in strongly on 8th with about 70 cents, average daily rainfall since about that figure. Heaviest fall to date yesterday, but wettest day the day before. *Crops.*—Berries swelling. A proportion of the "dubious-looking" ones seem to be coming on. *Labour.*—More coolies wanted in a few cases. *General Health*—Continues good.

Nellampatty (British). 15*th June*.—*Weather.*—Monsoon broke on 7th instant, and since then there has been incessant rain, ranging between 1 and 2 inches daily, till 7th day, when 6·85 was measured here. Total rain before monsoon 9·3 inches. Since monsoon broke 16·9, total to date 25·12. Very high winds, and everything just as usual with our old friend. *Crops.*—Berries swelling nicely, but I gather estimates are a little lower than they were from the blossom. Rice very dear still; 8 measures for Re.1. *Plant-diseases.*—Coffee looking well everywhere, and it is to be hoped that leaf-disease won't attack us, as it did last year, in July. *General Health.*—Very bad. A great many coolies are on the sick list with fever, while the European community is not much better, about a third of the district being more or less ill and off work. *Labour.*—All in in some places, and on others about half in.

THE LANGUAGE AND OPINIONS OF PLANTS.

WHAT are the opinions of plants? That is just your business to find out. And the more accurately you accomplish this feat, the more successful you will be in your business as a planter. In these days of widespread theory, rendered plausible to the many by the glib use of a scanty

stock of scientific terms, one is too apt to forget that the final court of appeal in agriculture lies with the plants. Silent but eloquent witnesses are these, quick to condemn empty theory by their bearing, and speaking with no uncertain voice on the disputed points submitted to them. Yet it is not given to all to understand their language. At times their judgments are given in enigmas, puzzles to be solved, not in the study, but in closer intercourse with the plants themselves. A keen eye, a mind trained in deductive reasoning, and a strong love for nature's secrets, are needed by those who wish to rightly understand and be understanded of the plants. We are all offshoots of Nature's one great stock. But separated by the growth of æons of time, we have lost touch with these once intimate, but now so remote, cousins of ours, the plants. Their reasons are not our reasons, their ways not our ways. We speak a different language now, and our knowledge one of the other is dim and incomplete.

Often has the striking likeness between plant and animal life, between the shrubs we cherish and ourselves, their tenders, half persuaded observers that the knowledge gained by the study of man may be applied with equal profit to plants. As a morsel of abstract reasoning, the truth of this conviction is undoubted. Yet in practice it fails, not from any inherent flaw in the principle, but from lack of knowledge to apply it. The art of reasoning by analogy is the art of reasoning from like to like. To make sure of our conclusions, our premises must be undisputable. It is here that sympathy must yield to logic, it is here that the keenest observation must be aided by reason. Sympathy begets a love of observation; by observation a vast number of isolated fragments of knowledge are gained; to piece these together, to make of them a connected and intelligible whole, this is the work of logic.

Of incidental interest is it to note a curious difference in such plant life as we are most familiar with, that distinguishes it from the higher forms of the animal creation. It is the bi-sexual nature of plants. We do not refer here to the well-known facts of fertilization, to the outward forms and ceremonies of what has been truly called the courtship of plants. It is to the deeper effect such bi-sexuality has on the character of the plant in its very nature. Practical, matter-of-fact readers may sneeringly deride a disquisition into matters of such remote practical interest. Yet, as we have said before, sympathy is one of the indispensable factors of success in even practical plant lore. The sternness of the male nature is, in plants, indissolubly linked with the more pleasing, changing moods of the softer sex. The complex nature arising from the combination affords innumerable points of interest for observation. And in proportion to the fascination of the study is increased likewise its intricacy. It is difficult enough to master the ins and outs of a mere man, twice as hard is the task of unravelling woman. When one nature holds both puzzles, their solution approaches the impossible. And in the many-sided facets of plant life, in its changeful phases, "nor age nor custom can state its infinite variety."

It is so difficult to treat a plant aright. Fixed laws of science may be applied for its well-being, food, air, warmth and moisture may be in the exact requisite quantities. Sometimes these all seem useless. Perhaps it is that the sun shines too brightly, perchance its rays are too shorn of their brilliance. Or it is the aspect that is unpleasing to its coy nature, the wind strikes a chill into its fibres. S mysterious, because unknown, trifle is wanted. If it coffee tree, it may delight your eye by its deep, gl foliage, with a deceitful air of vigour and fruitfulness. is all a hollow sham, a pretence, an empty nothingn Wearied with the unprofitable task, cold neglect and h treatment are now its portion. The mysterious elen wanting to its well-being is suddenly provided by absence of one or many of the profuse attentions it received. As unaccountably as it once failed to respon your care, it now responds to your neglect, by bounteous cr How, or wherefore comes your success, you cannot ea tell. To unravel the mystery of the wanton ways of plant, you must go round and ask of its companions. must obtain, and understand if you can, the opinion plants.

One will tell you one thing, a trifle and not to considered. From another, a further stray chip from mosaic puzzle will be gained. An end here, a fragn there, and in time and with patience, the most contradic pieces will fit themselves together, and the seemi insoluble mystery will be rendered plain and clear. language of plants is in sooth a system of intricate hi glyphics. One plant will answer your most eager quest with a reference to its neighbour. Others will come f with astounding assertions that seem worthy neithe credence nor observation. You can never rest satis with the knowledge you get from individuals even f the same race of botanical and practical identity. specimen will declare that all it wants is moisture, plenty of it. You pause, and test this assertion. there is no doubt that the plant is doing well with bount supplies of moisture. Yet with even a more confi mien, another individual puzzles you by proving tha very moderate amount of moisture is all that is nee You impatiently take a general vote, a sort of plebis from their companions. The answer is annoying; i inconclusive; it only proves what you knew before, it's a of six of one and half a dozen of the other. You try ag and try to discover the real, or some of the real, essen to plant health. You will find that the same result, in matter of health and cropping, will be due to cer combinations of varying essentials. There may be, perh a total of a round dozen, let us say, of essentials in cases. All of these may be present, and yet the resul failure. But a half may be found, and brilliant succes the puzzling answer. It will be found that success failure are governed by the combination of certain of essentials. These combinations are various, but luc their number is not infinite, and with patience may be learned in the fulness of time, aided by sympathy, obse tion and careful reasoning.

NOTES.

American tax on tea. The 10 per cent. war tax on imports, coupled with the effect the war itself, will have a most depressing effect on capture of the American market. The suggestion to su the U. S. Army with some hundred thousand pound tea is an excellent one as regards the advertisement. sure, however, to be strongly discountenanced by Government.

) juice: a good ipe.

A correspondent lately enquired how to make and preserve lime juice on the estate. The following been given us as being an excellent method :—

queeze limes, and strain the juice through cloth. To every of juice add one cup of sugar and boil it. Put it one side for half an hour, then add another cup of sugar and boil again. e, and it will keep for any length of time. Do not put in two of sugar at once, or the juice will not keep. It must be made ove."

fter a little while the top half of the bottle will be and the lower half clear, so shake the bottle before g.

---

rs. Cooper, Cooper l Co's amalgama-n.

We learn, says the *Home and Colonial Mail* of the 27th ultimo, that the proposed amalgamation of Messrs. Cooper, Cooper and Co's ness with a company to be formed acquiring a group Ceylon tea, coffee, and cocoa estates, to which we rred last week, includes, in addition to the Ceylon and ntal Estates Company, the Pallikellie estates and some e Rajawelle estates, also an extensive business in the h of England. It is believed that the combination will s a great stimulus to the trade abroad. The capital ne new company will be nearly three-quarters of a on sterling.

---

vation of stony d.

It is sometimes thought, but not often, that the presence of an excessive number of stones renders vation more expensive and difficult. Weeding, cer-y, is rendered a great deal more difficult and expen- but there is great saving effected in other directions. ns, for instance, both catch and sub-soil, are scarcely ed at all in stony land. The ground is kept so open ne stones that rain soaks in below the surface and s off naturally into the nearest nullahs. Forking, dig- and so on, are really superfluous operations on such For the stones keep the soil so open and porous that further attempts in that direction are quite useless. e soil itself is at all good, the presence of stones adds greatly to the value of the land, despite the extra nse of weeding and the discomforts experienced by master and coolies in working it.

---

coffee trade in erica.

In connection with our remarks elsewhere on establishing a market for plantation products in India, it d decidedly pay to import cheap American coffee to the way for our higher flavoured and more expensive es. East India coffee is not popular in America, writes xchange, and for this reason Sumatra coffee and Mocha e are worth more than is warranted by their intrinsic e. Coffee dealers say that fine Central American or mild growth costing 8*d.* to 10*d.* per lb. will roast er and make a more satisfactory beverage than East a coffee costing 1*s.* to 1*s.* 3*d.* per lb. The market es from 3*d.* to 1*s.* 3½*d.* per lb. for the raw bean. The ed bean retails anywhere from 4½*d.* to 1*s.* 10*d.* per lb. result is the greatest variation in retail cost, and a ce for the shrewd buyer to make use of the prejudice nsumers for Java, or Java and Mocha blended, to sell some other sort for these favourite growths.

Worms in legumes.

Complaints are constantly made of the appearance of worms, etc., in leguminous plants grown from apparently healthy seed that has been carefully stored in closed bottles, writes a contemporary. All leguminosæ should, ere being sown, be steeped in water, as hot as the hand can bear it, for half an hour previous to being put down. As it is stirred about it is astonishing to see the number of wire worms and others that come wriggling out. A good deal of misconception exists as to the vitality of the germ in all seeds and tubers. A curious instance of this came to light in County Galway, Ireland, during the worst stage of the potato blight in 1847-48. A tuber that had been dug from a plot seriously affected by the disease had been inadvertently placed on a hall stove, becoming almost calcined on the outside, the protruding portion of the *eyes* being quite destroyed ; out of curiosity it was sown, producing in due time some half dozen roots, which, on being microscopically examined, proved perfectly healthy.

Cattle trespass.

Cattle trespass is one of the greatest worries a planter has to contend against, and, excepting on the Nilgiris, there is little legal redress. A planter who has some little experience in these matters has written us a simple little plan to reduce the annoyance to its minimum. Instead of the highly illegal and high-handed way of shooting stray cattle, he pounds them on the estate itself. The errant cattle-keeper soon finds out where his cattle have got to, and does his best to persuade the "Doray" to give them up. But our friend insists on being paid the pound fine before he gives up the cattle. The cattleman is only too glad to get off so cheaply, and saved from a perhaps long tramp to the pound, with the consequent impositions from the pound-keeper. The fines are handed over to the coolies who catch the cattle, unless there is great disturbance of work, when half is retained to pay for the lost time. This *bucksheesh* makes coolies very keen on catching all the stray cattle on the estate, and consequently the garden in question is avoided with a holy dread by errant cattle-men. There is some doubt as to the legality of the procedure, but so far it has not been called into question, and it works splendidly. Care, of course, must be taken that the cattle are not detained for more than twenty-four hours.

Retailing coffee and tea in India.

There has been a great deal written on the subject of pushing the retail trade of tea at least in India. We have not up to date seen a really practical suggestion how to accomplish this desired end. It is hopeless at first to get the masses to take to either coffee or tea ; it is beyond their means, however cheap and nasty the qualities given. The upper and middle classes are the ones to be approached. Black coffee, and even the parchment itself, would be roasted and ground up into a powder, after the fashion of cacao husks. Made up into 2 oz. or ¼ lb. lead packets, planters would not find any difficulty in commanding a ready sale for this coffee substitute, and at very remunerative prices too. Better grades of genuine coffee, such as tailings and even No. 3, could be used for the same purpose, selling of course at a much better price. A similar trade could be done with tea, instead of selling the coarsest grades, such as red leaf, at the factory door for what it will

fetch. The aim in both cases, besides working for immediate profit, should be distribute the produce throughout the length and breadth of the country. To create a trade, which would afterwards be able to absorb without the least difficulty all our inferior grades of both coffee and tea.

Very few individual planters will, of course, bother themselves about the matter, but there is an undoubted opening for an enterprising firm or individual. We can confidently assure such that the support and assistance they will get from the planting industry will be a warm one. The requisite capital does not run into very large figures, nor need the warehouses or godowns be fitted with any very elaborate machinery.

The London Market. There has been no new feature this week, reports the *P. M. Review* of the 21st May. The auctions have again contained more than could be sold during the time allowed for them, but notwithstanding the very heavy supplies, the market has been a strong one, and quotations have in most instances been in favour of the sellers. Only a moderate amount of Costa Rica has again been brought forward, and this has in most cases sold well, at an advance of from 1*s.* for medium and common to 2*s.* for fine coloury. East India and Mysore have also attracted a considerable demand, and as the recent arrivals evidently show that only a small quantity more can be expected, prices have been well maintained, and for bold Mysore an advance of 2*s.* to 3*s.* above the prices of the earlier shipments of the same marks has in many cases been paid. In the terminal market hardly any business has been done, and quotations have scarcely varied.

Indian Teas.—The market shows no material change, as the bulk of the tea now coming forward is of indifferent quality, and has consequently met with only a moderate demand. The kinds most in request are those of earlier import, for which there has been a good market inquiry, and, as the quantity held by importers is extremely small, the principal transactions have been in second-hand parcels. Teas from 10*d.* and upwards are more inquired for, and as these kinds are not in very good supply and stocks are certain to diminish later on, a strong market with a further advance in values is not improbable. At the public sales of this week, out of the 18,451 packages offered, only 3,500 fetched 10*d.* and over, and show a considerable advance from the lowest point, while most of the growths were decidedly inferior in quality. The medium grades have also met with more attention, and all useful descriptions have sold readily at firm prices, pointing to the prospect of a stronger market in the near future. For the com kinds there is a fair inquiry for good liquoring sort steady rates, and there has been more inquiry of tea price, but with a limited quantity offering in leaf under 5¼*d.* Of the 18,451 packages brought forward, large proportion of 4,190 were withdrawn.

The "corner" in tea. Both Calcutta and Ceylon pa are now very much alive to dangers from the feared of "corner" in tea. Every the buying and distributing trade is getting more con trated into the hands of a few large buyers, and th have come to such a pass now that honest competition is almost a thing of the past. The Calcutta *Indian Plan Gazette* proposed some time ago that the planting indu should itself undertake the distribution of its teas, an away with the present brokerage system altogether. however, it has abandoned this scheme, and advises ins a general stoppage of supplies. In other words, to m facture as usual, but keep the tea stored in the fact instead of sending it home. Then, when the st at home are exhausted, there could be such an e enquiry for tea that the ring would be broken and free competition would be the order of the day reads well on paper, and as the Indian tea industr practically all in the hands of a dozen or so large compa it might be feasible, if it were not for Ceylon, not to s of China. As it is, the plan seems to us hopel impracticable. Our contemporary's original plan is r the best. To establish an association large enough to with the whole Indian crop would of course be very co Certainly a million sterling would not be a bit too l for the purpose. A beginning, however, could be mad a distinctly smaller sum, and its development woul merely a matter of time. The details of the scheme w it will be remembered, to form a company at home fo purpose of selling Indian tea direct to the grocery other distributing establishments. The planter w receive a fair market price for his tea in the usual way if a shareholder, on even a small scale, would shar whatever profits were made, competition would be couraged, and rates all round would rise to something their proper position.

Failing this perhaps elaborate scheme, a Ceylon p makes a very sensible proposal. In the old days, w Ceylon teas were new to the trade and in very smal mand, planters began pushing the demand by sen chests and quarter chests direct to their friends and tions throughout the length and breadth of the United K

COFFEE SHADE TREE.

Sun-dried Erythrina Lithosperma loppings, &c., contai ton :—

61·50 lbs. Nitrogen.
57·38 „ Potash.
14·92 „ Lime.
13·68 „ Phosphoric Acid.

Seed cured under Messrs. Sutton and Sons' advice.

Orders should be booked early for the 1898-1899 crop of seed the parent trees of above analysis at Rs.6 per pound conta about 2,000 seeds. *Germination guaranteed.*

Only thornless variety extant, and is not procurable anywhere from the

MANAGER, ARIENKOW ESTATE,
Shencot

This gave a considerable section of the public a ce to know what really good tea was like, and the and rapidly spread. Why not, our Ceylon contem- ry suggests, repeat the experiment? Let every planter a few half or quarter chests, perfectly done up in ets, to all their relations, telling them to insist on get- a like quality from their grocers.

e result would be that the public, which is now paying h price for a very poor article, would be supplied with r tea at very much the same price. Consumption d naturally increase. This scheme is, however, from its nature, merely a temporary alleviative. What is y wanted is to break the ring, and induce the freest of petition. A powerful distributing agency, acting on lf of the producers, who would be its shareholders, is best safeguard from the dangers of a close corporation.

LETTERS TO THE EDITOR.

JÂTS OF NILGIRI TEA.

R,—Some little time ago I ventured to write you a short cism of the ways and methods obtaining on Nilgiri Tea Planta- . It was a case of simple assertion on my part,—assertion I wish to support by reasons. I said the jât generally found nese hills was mostly bad. Such a statement requires sup- only in the matter of definition of what the term "good really means. Applicable to the industry of India and on as a whole, I presume no one will deny that the term ns those species or *jâts* of tea known by the name of Assam or ipur Indigenous Tea. Their main characteristics are their le-stemmed nature of growth, their large and many-ribbed es, the colour of the leaves varying from a yellowish to a glossy green. The characteristics of the tea made from r leaves are intense pungency and strength.

ut on the Nilgiris the term "good jât" has become, so to k, polarised. It means, or is held to mean by many, that which in their opinion is best suited to these hills can alone alled "good jât." I shall, therefore, adopt the more accurate , when speaking of Assam or Manipuri tea, of indigenous Indigenous tea is mostly conspicuous by its absence on the iris. The reason is not far to seek. It is thought to be not kind best suited to the district.

or this district, like some other insignificant localities in er India, may be said to be devoted almost altogether to plying the local market. The sound packet trade is the be-all end-all of nine out of every ten Nilgiri gardens. When I e this, I do not intend to sneer. I am simply stating a fact. v the demands of the local made are very different to those the London market. The very terms of quality, flavour, p" and even of grades, bear a very different meaning in ia than they do at home. Coarse plucking, lack of point, of strength and pungency, so fatal to London sold teas, do matter a jot to the consumer out here. Certain of the above nts, indeed, are positive recommendations. Much pungency is itively disliked. A deep colour, a high-fire and a soft liquor the factors of success in the local trade. In London these lities go by the name of muddy colour, burnt flavour and ntless liquor. It is obvious that what will best suit a Nilgiri l-trade garden is a hardy, quick-flushing plant. Indigenous will give too strong and pungent a liquor, and must moreover ended with more care than it is the fashion here to bestow tea. A hardy quick-growing and good-flushing hybrid, refore, is undoubtedly the best jât for local-trade gardens. t is not difficult to understand when a garden finds the l trade too congested to relieve it of its crop, and send its surplus to London, that the prices obtained are so thoroughly unsatisfactory.

I may, perhaps, pursue this subject further in another letter.

Yours faithfully,
A NILGIRI PLANTER.

GENERAL ARTICLES.

THE U.P.A.S.I. SECTION.

[UNDER THE CONTROL OF THE SECRETARY, U.P.A.S.I.]

THE following is Mr. O. Newport's fourth letter regarding Ladybirds. It is dated Brisbane, 22nd May, 1898:—

I am in receipt of your letter of the 13th April, for which many thanks.

As mentioned to you in my last letter, the funds I have in hand will be ample, and I shall therefore not need any more while away from India.

There is no need for me to write you *re* packing and transit, I think, as I am not sending any consignments before I come. I certainly think *viâ* Tuticorin the better route and will come that way.

With regard to the share of the consignment that is to be sent to the Nilgiris, I could do as the Chairman suggests if thought most advisable. I think, however, that it would be better if I were to divide the consignment at Dindigul, leave half on ice there for a day or two, while I took half up to the Pulneys freeing them and leaving them in my brother's charge there. Then returning and taking the other half to the Nilgiris.

I think this most advisable, as the consignments will have to be examined for parasites on opening. There is no need for me to stay long on the Nilgiris, and I could give the hints for propagation better verbally than by letter.

Distribution is a matter that will come later on, I think. Once on the Hills, a dozen or two of each kind could be sent round to any interested parties to experiment with if desired without any trouble, but it would, I think, be better to let the Ladybirds propagate first and distribute them after acclimatization.

I beg to report that I have at last succeeded in getting a chest that will keep at a fairly low temperature, *i.e.*, above 25° to 35° F. It has been a great deal of trouble and entailed a lot of work and more worry. I hope, however, to be able to bring out my collections safely and alive. I have been collecting steadily and have some 4,000 specimens, chiefly of the three kinds mentioned in my last letter. I trust I shall be able to produce most of these alive in India, but the most trying time is to come, *i.e.*, the voyage back. It will be exceedingly difficult work to keep my brine chest working steadily all the time, but I will do it if it possibly can be done.

I have taken my return passage in the Orient boat *Oroya* leaving Sydney on the 25th instant. I leave here, therefore, on the 25th instant, and hope to arrive at Colombo on the 17th or 18th June.

I will telegraph my arrival to you from Tuticorin.

You will get this letter, I think, a week or so before my arrival. Would you kindly write me to Colombo (c/o Orient Line Agent,) or to Tuticorin (c/o B.I.S.N. Company Agents) informing me where I can obtain ice in Tuticorin, also mentioning any other instruction you may have for me. I anticipate no difficulty about ice at Colombo. On second thoughts, I think my best plan would be to telegraph from Colombo to Messrs. G. Mengel & Co., Dindigul, for a consignment of 50lbs. or so of ice to await my arrival at Tuticorin in any case, (whether I hear from you or not.)

On my arrival in India I shall proceed direct to Dindigul. If you wish to reply to my telegram announcing arrival at Tuticorin, would you kindly wire me at Dindigul, c/o my Agent, S. Rungasawmy Naidu?

I shall not have time, nor will there be any need for me to write again before my arrival.

THE *Madras Mail's* Simla correspondent wired on 15th instant:—

"The Government of India is still awaiting the result of numerous references in connection with the Southern Indian Planters' Enquiry Committee's report, and there is no expectation that these will be received soon enough to enable the Government of India's decision

upon the very large and important questions involved to be issued in time for the Planters' Annual Meeting at Bangalore in August."

This is certainly bad news for our readers. However, if the work is eventually *well done*, a little delay will not be matter for regret. It is to be hoped that the further references that have to be made will result in Government being able to pass final and satisfactory orders.

* * * *

Mr. Newport arrived at Tuticorin, with the ladybirds he has brought, on the morning of Friday, the 17th instant.

JOTTINGS FROM MY NOTE BOOK.

Fire and flushworm. Some months ago I had occasion to burn a couple of tea bushes which contained hornet nests. It was done about a month after the field itself had been low pruned. The job was a thorough one, as I piled up dried prunings all round. The ground itself was charred some two or three inches deep. This month the burnt bushes are flushing most vigorously, and are very nearly equal to the surrounding trees, which were only low pruned. I have lost scarcely nothing in the way of flush; in fact, only two tippings. In a month or two more, to judge from the splendid thick growth of flush from the roots, I expect the burnt tea will be far superior to that merely pruned. The jât,, by the way, is a fair hybrid. The curious thing is, though, that flushworm is just as bad, if not worse, on the burnt tea, than on the pruned bushes.

This does not teach one very much though. For, although the flushworm may pupate under the bush, below the surface, there is nothing to prevent the perfect insect from attacking trees hundreds of yards away from its resting place. So that although the fire may have killed off every poochie under that particular tree, the surrounding trees offered asylum for hundreds more. The only way to test this procedure thoroughly is to experiment on a whole field or patch as remote as possible from any neighbouring tea.

Fire *versus* the knife. I must say I am rather taken with the idea of using fire instead of, or rather in addition to, the knife, especially in old, tangled and neglected tea. I mean to try my worst field anyway. But I shall do it *pucka*. First a couple of men with a bill-hook and a cross-cut saw. With the bill-hook roughly trim the branches that get in the way of the saw. Then saw right to the level of the ground. Following these two men will be a third, with a mamoty and a big pruning knife. He will clear the earth away from the stump, and lay it bare some inches below the surface of the soil. Then he will, with his knife, round off and smooth the cut of the saw, going as far below the surface as he possibly can. Perhaps there ought to be three gangs to every row. First one man with a bill-hook and mamoty to lop the branches off and clear away the soil so as to let the saw get down below the surface. Then the two cross-cut saw men. Lastly, a man to trim the stumps, coat the cut surface with some suitable paint perhaps, and lastly to cover up the stumps well with some three or four inches of earth. This is to prevent the fire-burning the stump itself. Lastly, when all the prunings are nice and dry, and a fair wind is on, I would set fire to the whole show and burn it to ashes. Some old prunings of course would not burn out altogether; these could be collected and burnt in stacks, or else for fuel, for the tea-drier or by the coolies. Anyway, must be got rid of. A deep forking a week afterw would allow the soil to retain the valuable ash, other carried away by rain. The only objection to forking be the young shoots are up is that a good deal of dam may be done by striking the forks against the stumps. little care would avoid this danger.

The result should be grand. In four months or so would have a perfectly new field of tea, to be trained treated in any way you like. Ten to one flush worm, red spider and a hundred other pests would be cleared for a few years at least. The clogged old channels of old tea bushes would be exchanged for perfectly new ways, and what is more, a little careful handling out of superabundant shoots would form ideal bushes for fu pruning.

Handling tea. This brings me straight of rather a novel subject, *i.e.*, the h ling of low-pruned bushes. As a rule, nothing is don shape a low-pruned bush except by subsequent prun I don't see why one should not be able to commence op tions at once, as soon as the bushes are fit for tipping should be inclined to begin tipping a great deal sooner is usually done. Allow, say, six inches of growth onl remain on the bush. Then remove bodily the exces young shoots, leaving one or two only together. Espec clear out the centre. This early tipping will make the s throw out from the lateral buds, giving an immediate sp to the bush. Then allow a couple of weeks to elapse, repeat the operation, leaving an additional six inche growth. Another fortnight repeat, and then ordinary, careful, plucking may be introduced.

This will save an enormous amount of bother herea in pruning. For all low collar pruned bushes, even of good jât, throw up such a dense mass of sub-collar and suckers that, unless handling is undertaken, the resul bush is more like a big grass tussock than a shrub. W hybrids this is notably the case, and as to Chinas, enough to make an angel weep.

To train Chinas. It is an awful task to train C bushes in the way they should g and when they are old and hardened sinners, the job is v very hard. Ordinarily low pruning has only a very s effect at betterment; indeed, I often think it is worse t letting them alone. A passable way is to leave on dozen stems or so, say a foot long or less, and clear the rest below the surface. It's expensive work this. I inclined to think that a rough hack down to the grou piling the prunings over the site and burning them stri *in situ* might be of use. The action of the fire would out the mass of suckers and thread stems in the centr what was the bush. Subsequent growth would proba not be quite so dense, and by avoiding low pruning taking all possible care to preserve the fresh stems, plaguey Chinas might be wheeled into line. Digging t out and replanting with good jât is possible, but not in pensive.

I should not attempt to dig out each bush singly undertook the job at all. I should prefer beginning, say a cross drain, when the upper side is some two feet ab

lrain level. Then I should have the whole block dug to that level, every bit of root or stem above that to be carefully picked and burnt. The cost would uite fifty rupees per acre, but not more, I think. ng for the new plants would be unnecessary.

---

l cultivation.

Is there no economic tree at all that might be interplanted in tea, a view to getting a second crop to rely on? I don't mean e that will not only do no harm to the tea, but actually fit it, and at the same time give remunerative crops the minimum of attention. That's all bunkum. But tree that, if carefully planted at a good distance , would not appreciably injure the tea, if manured cultivated. In the low country, rubber seems just the r. But higher up, fruit trees and camphor are about nly plants of any importance. Coolies would give an l amount of trouble with the fruit, and as to camphor, can't get any plants or seed anywhere.

---

vation of steep ates.

My estate is a very steep one, and how best to cultivate it is a problem that has been worrying me a long time. Terraces I don't think would answer, gh I am open to correction on this point. Digging is tically impossible for fear of wash, renovation pits are arous inventions, and yet the soil must be kept open. inclined to think that deep down drains or trenches, wing the steepest line of descent, would not be a bad The drains must be narrow, or they will dry the oo much. They must be deep, or they won't aërate it iently. They must be fairly close together, or their t will not be great enough. I should begin, I think, aving a drain every other row of trees, say two, or even foot deep, by one or one and-a-half foot broad, the ower the better. There would practically be no scour e drains were every other row, and ordinary side catch s provided to carry off excessive rains. These catch s should be big and deep, by the way. There would e much objection either to block these down trenches tervals of every few trees by leaving, say, a foot or two rth undug. Water collected above would very soon plate through the wall. There is one thing, though, ast this. Silt, leaves, &c., would soon fill up the ends, *then* a big shower might do damage. No, on second ghts, I should say it were best to keep them open from o bottom.

might well be in some districts that the ground would oo dried up. Well, in that case, I should dig the s just the same, but have them all filled up at the end he monsoon. Next year I would dig the drains in alternate rows, and likewise fill them up. In filling in, y stone handy, large or small, should be thrown in at ottom of the drain. If it were possible to make large on the estate, something like an exaggerated country I fancy it would pay well to use them. In that case, y twenty feet would be about enough to have a drain. t is the precise object of all this expense? Well, let ok at what the cost would actually be, letting the tiles e. The actual cost of digging drains, say, two feet deep ne foot broad every alternate row would not be more than 30 rupees. Allow ten rupees an acre for the saving of forking, &c., and the extra cost is reduced to Rs.20 per acre, or Rs.40 for two years. Well, for this sum, you have your soil kept perfectly sweet and open. Nitrification will go on at double the rate it did before, and every bit of manure you put down will be turned into soluble plant food, instead of half being wasted as heretofore. Then there's the permanence of the work. You needn't trouble about anything more than keeping the land clean. It's a thing, though, that has to be tried and not talked about.

MANAGEMENT OF LABOUR.

A JORHAT planter, writing to a contemporary, gives his ideas thereby on the management of estate labour. I remember years ago it was my own idea to supervise everything myself, and I thought nothing could be right unless I had a finger in the pie. I happened to be on a trip round seeing some well-known gardens and had a long talk with an old well-known Assam planter, who has now gone to the happy tea lands, about managing coolies. His argument was that natives could manage natives and get more out of them than Europeans could; and besides, he said, if you paid your native establishment, why not make them work for their pay, instead of you doing their work. Again, if you make a certain head native responsible for the coolies, you have only one man to deal with, and it is far easier for you to deal with one man than with hundreds. Again, your head man begins to know your way of working, and should you be taken ill or have to leave, the work goes on the same as usual. Again, if the European is always with the coolies, the sirdars get lazy, as all responsibility is taken from them, besides the coolies lose their fear for the sahib, and when he is not there do not obey the sirdars, &c., as they should. These were the main points. I was so impressed by all this, that when I got back to my garden I by degrees changed my way of working and have never regretted it. I know men will at once say that your head mohurrir will have all the power and make full use of it, and that you yourself will be a nonentity. Of course, if you do not know your work there is every chance of this happening, but if you know your work well, and your mohurrir knows that you do, he will not for his own sake try his tricks. It is much better that the European, the head of the whole garden, should be kept in good health for the good working of the garden, for if he goes down sick, it is like removing the governor from an engine, it then works erratically. Of course, I do not mean to say the European should leave everything to his natives and sit in his long chair in his verandah and believe everything his mohurrirs, &c., choose to tell him. What I mean is that he should go round his work and satisfy himself that his men are working properly and not interfere with them if they are doing well. Even should they be doing not just as you yourself would do, but still are doing the main thing well, I would not interfere then, but would another time suggest to the man in charge how you would like it done. By doing this I find the men begin to *think* about their work and see among themselves who works cheapest. Over and over again when I have wanted any certain piece of work done, I have suggested so many men being taken to do it, but my man would say, "Oh, sahib, I do not want so many people, and I will promise to have it done for you." Another thing. I always tell my head men what I am striving to do in the garden work, so as to let them see how one work dovetails into another, and it is wonderful how they begin to understand and give valuable suggestions. Of course, I do not mean to say all this is done without many worries and vexations of spirit, but still I say if you can manage the above, it is better than acting yourself as head mohurrir, sirdar, and line chowkedar

all rolled in one, and saves one an immense amount of tear and wear.

VANILLA.

THE large amount of atttention given recently in America to this article, and which called forth five papers on the subject before the New York College of Pharmacy, is not explained, as far as I have been able to learn, by any incident of trade such as a deficiency or plethora of supply. That vanilla, however, deserves a great deal more of attention than it receives from growers is readily conceded. The plant is an orchid that flourishes in low levels between 1,000 and 2,000 feet above the sea, which explains its neglect by European enterprise. It is cultivated on the slopes of the Cordilleras, in Java, Mauritius, Tahiti, the West Indies, Mexico, Zanzibar, Seychelles and Réunion. The locality in Southern India, which appears best adapted for it, seems to me to be the few miles of country that intervenes between the town of Mettapollium, the railway terminus for Nilgiris, and the foot of the Coonoor Ghaut. Its elevation is exactly that in which the plant is known to thrive. The areca nut, on which it luxuriates, abounds in the locality. The air is humid and cool and laden with the fragrance of fruit and fruit trees that grow by the way-side, and that is inhaled with pleasure by the weary traveller as he completes his hot journey from the plains to his mountain destination. Beyond these natural advantages, I am not aware that the locality is specially adapted for vanilla, as no attempt has yet been made there to grow it—nor have I heard that any other locality was ever tried, so that my opinion is merely an impression, and no more.

The leaves of the vanilla are a thick glucose, oblong in shape, and the plantations a height of 45 feet, yielding a crop in the third year and continuing to bear for 30 years, from 40 to 55 beans, which are ready for gathering in the months of April, May, and June. The harvest, however, must be before the beans attain complete maturity and before they lose their greenish tint. According to the method of preparation pursued in Mexico, the beans, after gathering, are exposed to the sun wrapped in blankets; they are afterwards stored in boxes from 12 to 15 hours, by which time they acquire a coffee colour. To arrive at the proper brown tint desired, two months' preparation is necessary of this alternate drying and wrapping up, and when the process is complete, the beans are stowed away in boxes of 50 each and despatched to market. There is another method of preparation by which 500 or 1,000 in beans are tied in a bundle and steeped in boiling water which has the effect of blackening them. They are then exposed to the sun, rubbed with oil to prevent the stem bursting and wrapped in cotton wool moistened with oil. When drying, a sticky dark liquid exudes which must be rubbed off: the loss of weight thus caused amounts to about 25 per cent. of the weight of the beans. The best pods are from 7 to 9 inches in length, and if properly prepared should have a "silvering" all over them which is produced by a crystallizing salt called "rime" that forms on the outside. Half the world's requirements in the way of vanilla is supplied by Réunion,—Mexico being the next in importance as a country of export. France takes a large quantity of vanilla, but both the supply and demand fluctuates. Vanilla is treated as a spice and is aromatic. The roots are very liable during cultivation to attacks by ants, from which they must be preserved. The plant has a tendency to spread literally, which should be encouraged by placing bamboo tatties for it to extend over. For the curing, a dry open shed is required, and the pods should be arranged in it on tie dry gradually. When packed, each bean is separately wra in clean paper. All the operations in the curing proces very delicate and must be performed with care. The must be soft and retain all the "silvery," or it will be rej by the buyers as inferior. The tendency to split must be fully watched and prevented by the application of oil, repl in the sun as often as it is necessary till the desired darkn colour is obtained. The sunning takes as many as 20 days, and if the weather renders the drying to be perfo under shelter, equal care is needed in the regulation o temperature of the shed which should not fall below 95 de or rise above 125 degrees. It is usual in drying with art heat to complete the process in the sun. The flowers o vanilla need fertilizing and the plant seeds freely.—*The Pla*

NEW SEASON FOR CHINA TEAS.

As a sign of the commencement of another season for teas, it was cabled, and duly reported by us in our last that the market had opened at Kiukiang on the 9th instan that settlements at Hankow had already been made at above those ruling there in May, 1897. Those engaged i China branch of the London tea trade will, therefore, soo looking forward to receiving fresh supplies of their fav description of tea; and a new interest will be awakened i character and extent of the new crops in the "Flowery L for 1898-99. Most parties agree in stating that, so far as present known, the entire crop promises to be larger th 1897-98, which is satisfactory, as in previous years ther been a heavy falling-off in the production of China tea. T proved by the fact that in 1897-98 the total crop did not more than about 582,000 half-chests, as contrasted with 64 half-chests in 1896-97, and 811,000 half-chests in 1895-96.

It is, however, too plain that if the new crops of China t turn out well, the full benefit to be derived from this fac not be enjoyed by the British consumers, but rather b foreigners who prefer that kind of tea to any other. Thu that, whilst the agents acting for English firms are s looking on there, the Russian buyers at Hankow are ac securing all the best supplies as they arrive, and a good bu is being done on their account, whereas last year they op very cautiously at the outset. As evidence of the dimi rate of consumption of China tea in this country, it m mentioned that the deliveries for home use during the firs months of 1898 have been only 5,127,950 lbs., against 6,19 lbs. in the same period of 1897, and 6,535,300 lbs. in Singularly enough, the quantity of China tea exported fro United Kingdom in the four months ended April 30 last prised 5,812,940 lbs., or 684,990 lbs. more than the a consumed in these isles; but the foregoing total of 5,812,9 was lighter than those pertaining to 1897 and 1896, when four months 6,038,366 lbs. and 6,149,922 lbs., respective China tea were shipped hence to foreign parts. The expo all other kinds of tea together (Indian, Ceylon, &c.) to da not embrace above 6,466,520 lbs., in comparison with 5,58 lbs. and 4,048,150 lbs. in the two preceding years, showing China tea, in this respect at least, takes the lead with sh to the Continent and elsewhere.

The new season opens with a London stock of old Congo of the smallest that has ever been seen, it having been at t of last month only 6,778,650 lbs., as opposed to 8,101,75 in 1897 and 13,601,350 lbs. in 1896; and with this deficie the available supply on hand there is a corresponding po

MILLIE & REDMOND, late P. THOMPSON & CO., *Ootacamund, Engineers and Contractors.*

assortment on offer. Such being the statistical position na tea, there is some reason to hope that, when the coming ls of new Monings and Kaisows appear on the market here, vill meet with a better reception both from the dealers and ers than they did last year, and so impart a healthier tone trade all round. A similar feeling of hopefulness was ex- d in May, 1897, when there was a good deal of talk about hine-made" tea as a novelty in Chinese manufacture, and possibility of its taking the place of Indian and Ceylon, delicacy of flavour, united with a little pungency, was an ial condition with the purchaser. Yet it was not the s anticipated, and the chief manufacturers at Foochow d losses of 3*d.* to 4*d.* per lb. on the red leaf teas sent to n. The truth is, the home trade did not take very kindly m, not liking to try the experiment of them in their blends, for fear they should not exactly please the tastes r customers; and, worse than all, exporters would hardly t the teas turned out under the new process. But, not- anding these reverses, the makers of these teas have no ion of giving up their enterprise, from a conviction that re an undoubted improvement on the old style, as the teas uch admired by some tasters and drinkers for being thick, , and full of delicate aroma—a flavour which is greatly ed by consumers of a more fastidious class. When more known and appreciated, it is possible that China teas ced from the machine will find their way more freely into nption and thus help to fulfil the predictions originally d concerning them.—*The Grocer.*

SOME DANGERS OF IRRIGATION.

advent of the South-West Monsoon may not seem a particularly well chosen for the discussion of such a t as irrigation. Nevertheless, many of the points in connection with drainage are fully applicable to esent season.

a late number we had occasion to remark on the value gation to tea in the matter of ensuring larger crops. lisadvantages of the operation alluded to then it is ur intention to discuss. The best quality and greatest ity of flush is produced in the warmer and showery s—not monsoon time, be it observed. Likewise ged hot, dry weather, under ordinary circumstances, s flush, and what there is is poor in quality. Unless lly managed, irrigation will tend to produce a much flush than the bush can safely give, and with conse- loss in the quality of the tea. While, up to a certain water aids greatly in solving inert plant food in the et there is a danger of the plant exhausting the sooner than the loss can be made good. So that the soil is of exceptionally rich character, manure is lispensable adjunct to irrigation. No one will grudge tra expense of course, as the increase in yield is so n and rapid. Manuring brings us to an interesting t, *i.e.*, the best manner of application in conjunction rrigation. This depends of course on how the irriga- carried out. If it be the ordinary way of leading into pits dug between every few plants, it is obvious anure should be neither in those pits nor close below especially in the case of poonacs and the like. gain is surface manuring to be advocated on steep Eye-brow pits above, or one side of the trees, are os to be recommended. The principle underlying this is of course that the moisture should *ascend* to the manure, and not, by rushing through it, carry its soluble portions out of the reach of the plant roots. It would be preferable, indeed, were the labour available, to defer the application of manure until, say, a month had elapsed from the first watering. In this way the manure could be easily applied so as to avoid all risks of wastage.

The two real dangers of irrigation are, however, more serious by far. Firstly comes the more obvious danger of over-soaking the subsoil, stopping efficient drainage, and blocking up the pores of the soil; the formation, in fact, of sour soil. Acidity in soils is not only the cause of the suspension of fertility, but actually destroys the valuable nitrates present, resolving them into their original elements. Perfect and deep drainage, therefore, is essential, and the flatter and heavier the land, the more imperative its claims. Irrigation pits on steep land should be dug in rows running *down* the hill, so that the contents of each pit may be allowed to drain naturally and easily into the one below it through the intervening subsoil. Water, of course, would not be applied from top to bottom, as this would scour the land dreadfully; it would, on the contrary, be allowed to flow down one main channel only, and be turned off into side rows, filling each pit gradually. As soon as the end pit was filled, the water channel would be blocked and opened a little lower down. A single down main channel would be necessary for each block. If made deep and narrow, the scour would not be appreciable. Care should be exercised that but a small volume of water should run down this channel.

The other evil, and none the less real from its seeming remoteness, is the surcharging of the soil with noxious salts deposited by the irrigation water. The well-known barren salt wastes known as *reh* or *usar* land in Upper and Central India afford striking testimony of the fatal effects of badly managed irrigation. If thoroughly efficient drainage be provided, the harmful salts will be carried away by the surplus water. Should, however, the drainage be insufficient, or should there not be surplus water available, the salts will remain and accumulate to a most harmful extent in the soil.

It is therefore clear that, while irrigation under intelligent management may be productive of great benefits, grave dangers attend its unskilled use. We have so persistently advocated the claims of irrigation in the past that it must not be thought to have changed in our convictions. In pointing out the dangers to be avoided, we hold we are doing the cause benefit. While advocating precautions, we are far, very far, from discouraging experiments.

BEE-KEEPING ON THE NILGIRIS.

Honey, which ought to be a most profitable article of trade, is conspicuous by its absence, except when sold by some native who has come across a hive by accident. A few years ago, before forests were reserved, game laws passed, etc., honey found its way into the station and was readily bought up by consumers who, not knowing the history, swallowed the proverbial "peck of dirt" in happy ignorance; had they had an inkling of the manipulation and rag-straining process, it is very doubtful if they would have looked at it even. The Forest Department promptly put a stop to the rifling of hives when it

[w 15-11-98.] *Lombard St.*

essitated a jungle tree being hacked to pieces, and it also nd honey and wax a proved profitable form of revenue. The me and Forest Act came none too soon, and the poaching daga and pariah discovered a 15-rupee license rather beyond means, and with the discovery, the sale of honey in the station antly ceased.

But not so in the Wynaad and other jungles. There the rmous quantities of wax and honey tempted the Kurunta and ila to pay the necessary sum and secure a rich harvest, which y do to this day. Or failing this, the same is collected for vernment by the Forest officials and their subordinates.

n the Wynaad one of the chief sources of the honey-supply ound under the arches of the great bridge spanning the river t divides the Mysore territory from the Wynaad. Countless arms cluster in immense bunches underneath, and the combs simply gigantic in size, often measuring 3 to 4 feet in length over a foot in depth, fining off to 4 or 6 inches at the edges. ch cell is three-fourths of an inch deep or more, and wide in portion. A single hive has been known to contain several ge earthen water pots, such as native women use. This rticular honey is made by the large giant bee, a most savage d fierce variety, as remarkable for its size as its sting; in fact, y people would care to own a hive of them in their garden; , easily roused, they attack man or beast with a ferocity that nequalled, following the victim for long distances with an gry roar that is as terrifying as it is strange. This bee will en build on trees, hanging the honeycombs on to the larger nches. Close to the trunk, a dozen hives will settle in a tree, d woe to him who seeks shelter under the boughs and rouses ir ire by smoking or lighting a fire, or in fact doing anything tating to apic sensibilities.

A well-known forest officer, who ought to have known better, nped under a famous mango tree in the Wynaad, a tree noted its hives. Preparatory to lunch he threw himself down, and a cheroot. His unfortunate horse, tethered close by, cropped the grass near, when without an instant's warning a cloud of s came down like a whirlwind. It was a case of each man himself, and the devil took the poor horse; tied, with no nce of escape, the poor brute in a moment became the object ttack. In vain he rolled and screamed in his agony, his iless tormentors wreaked their rage upon his form, till th mercilessly released him from his sufferings.

n Ootacamund itself the large bee seldom settles, and when does, he lets people know it; the post office or church offer al attraction, and he settles for a while, but his presence is tolerated, and the hive has "to move on."

To hear a hive migrating is one of the most appalling sounds ceivable: the extraordinary roar of the musical hum moves rhead like an express train, but it is the fearful menace of tone that terrifies; imagine several swarms infuriated eeping down on you at once. Brave indeed need the man be o can keep his head under such trying circumstances!

To return to bee culture. It is needless to remark that no cares to hive this particular branch of the apic family; and, the honey is nothing like so good or rich as that of medium-sized kind, the preference is always given to the latter, and this bee, not unlike his European cousin, is a tractable steady worker; he has his fancies, and will leave you in the lurch if he thinks it time to change his abode, and he will drink up all his honey if the weather promises to change; but with all his vagaries, he can be tamed and made to produce a very fair quantity and quality of honey. One fact has always to be borne in mind, and that is, that when the wild Lobelia is in blossom, to avoid eating honey. The rank poisonous nature of the flower is communicated to the nectar, and the honey is not only deleterious, but distinctly unpleasant in taste, catching the throat and inducing giddiness and nausea. Birds, however, do not seem to mind, and they may be seen swinging on the flower-heads, having a royal feast. Besides the Lobelia, the blossom of the Acanthus is apt to cause illness if the honey is eaten. These two flowers seem the only ones that affect the quality. After a hive is disturbed, or on a swarm separating, a curious feature may be noticed, namely, the suicide of the drones. These unfortunates, bereft of hope, commit *felo de se* in a way quite their own. After buzzing desperately around, they inflate their bodies till the wings in the abdomen separate, and with a little splutter the contents burst out, and the bee falls dead. Whether other bees do this or not may be known or otherwise, but there is no doubt of the fact. Of course, it may be traced to stings inflicted inside the hive, which would drive the injured creature out to buzz about in pain, and the stung portion to give way in the efforts made to find relief.

A third kind of bee is a tiny one, very little larger than a house fly. This one frequents the slopes of the hills and is very common on coffee estates, where its presence in flowering time is a god-send to the planter, but no cooly will spare the dainty little comb clinging to a twig with its little fan below of young bee; all find their way into the greedy maw. This rifling of hives on estates ought to be heavily punished, for so much depends on the blossom being fertilised by bees.

The honey of the small bee is most fragrant, rich and sweet, the nest is built in the open air inside some thick bush, thorn for preference, for the little bee has a horror of hawks, and several of the hill birds worry its life out. An inquiring hawk will pry into any bush in search of a hive, and the "wait-a-bit" and "Mysore thorn" and one or two others seem to deter it in its quest. In bygone days the Badagas were in the habit of bringing the honeycombed twigs, and delicious they were for a breakfast dish, often found in all sizes, from as big as a goose's egg to a roly-poly pudding; these combs could be either cut off or eaten off the twigs as you would pick a bone; the prices ranging from an anna to three or four at the outside, supplied you with this delicacy that is never seen in the present day, not that they are no longer found, but the heavy fine deters the finders from selling the combs, so the honey is eaten on the spot.

Bees have been introduced at different times, and at this present moment there are dozens of swarms that have got away and are in the sholas about, but no one seems to be able to give an intelligent history of their introduction or what they did; planters at Kotagherry have the credit of keeping Italian bees, but though Kotagherry is but 16 miles from Ootacamund, no one knows anything that goes on there, except perhaps a dish of scandal, and that as often as not goes further, even the sea in no way cutting off the news.

Agriculture on the hills may answer better in warm dry climates, such as Kotagherry, Coonoor, Kuthully and other places, and the residents have kept the medium-sized bee with fair success. There is no doubt that a warmer climate would suit both the indigenous and imported varieties better than Ootacamund itself, for the monsoon is decidedly trying, and the flowers have no chance of blossoming, while the honey is all washed out.—APIS INDICA in *Indian Gardening*.

DISTRICT ASSOCIATIONS.

KANAN DEVAN.

Minutes of Annual General Meeting, held at Manalle on 28th May, 1898.

PRESENT:—Baron J. vonRosenberg (*Chairman*); Messrs. W. Milne, C. N. Thomson, R. F. Russell, A. H. Mead, C. Burn Murdoch, J. Hamilton Hunter, T. W. Schmid, R. Hedger, H. M. Knight, W. D. Martin, A. H. Sharp (*Honorary Secretary*), J. S. Sealy (*Honorary Member*), L. Davidson.

The Chairman, in a brief introductory speech, revised the past year. With reference to the Currency Commission, he pointed out the dangers now menacing producing exporters and the certainty of ultimate reaction on importers and Government as well. He asked the Association to pass a vote of thanks to the Chairman and Secretary of the U.P.A.S.I. for the prompt measures taken to ensure representation of planting interests. As to the report of the S.I.P.E. Committee, he expressed a hope that something definite as to the Supreme Government's intentions would transpire before the Annual Meeting of the U.P.A.S.I. in August next. After reference to some local matters, he asked the Association to welcome the new District Magistrate, Mr. J. Sealy, and to elect him an honorary member. He considered Mr. Sealy's appointment a kind of recognition by the Travancore Government of the predominating importance of the planting district, while regretting that the Central Travancore Association should have been left without a European Magistrate. It was to be hoped, he said, that the Travancore Government would not confine its recognition to magisterial matters, but would grant finally and fully that help in roads and communications which it had extended to the other planting districts of Travancore.

Minutes of last meeting were taken as read and confirmed.

The accounts for the past year were passed, having been circulated previous to the meeting.

The following office-bearers were elected for the ensuing year :—

Chairman.—Baron J. vonRosenberg.

Honorary Secretary.—Mr. A. H. Sharp.

Committee.—Messrs. W. Milne, H. W. Knight, L. Davidson, and W. D. Martin.

Roads and Communications.—*Read* letter from the Collector of Madura giving cover to copy of Proceedings of the Public Works Department, Madras Government, ruling that a new road should be constructed between Bodinaikanur and the Government of Messrs. Findlay, Muir and Co.'s proposed aërial ropeway at Kotagudi. The District Board agrees to pay one-fourth of the cost of this road. If the planters will contribute as much, His Excellency the Governor in Council will be prepared to provide the value from Provincial funds. It also stated that the insanitary condition of Bodinaikanur will be considered in the Local and Municipal Department. It was proposed by Mr. Knight that, while thanking both Government and the Board for their offer, His Excellency the Governor in Council should be requested to reconsider the question of asking the planters to pay one-fourth of the cost, taking into due consideration the large amount of money now going out of the district into the Madras Presidency. *Seconded* by Mr. Hedger and carried.

No. $\frac{508}{\text{Board}}$ 17-5-98.

G.O., No. $\frac{2407\text{C.}}{5\text{-}5\text{-}98}$

Read copy of resolutions passed at Proceedings, No. 18, of 1898, of the Madura District Board, viz. :—That the Board resolves to put the road as far as Bodinaikanur into good order as far as their funds permit, and that they would bear one-fourth of the cost of the proposed road from Bodinaikanur to Kotagudi, and that in the event of the new road being made, the present allotment for the Devikulam Ghât will be withdrawn.

Resolved that the Honorary Secretary continue to correspond with the Board on the subject, and that with regard to the proposal to withdraw the annual allotment from the Devikulam Ghât, this Association is of opinion that the members of the District Board must be labouring under a misapprehension in regard to the necessity of continuing their vote for the upkeep of this Ghât road. This Association is of opinion that the large amount of extra t being thrown on this road through extension of cultivation alon course justifies the hope that the allotment will, in future, be incre rather than diminished.

Read letter from the President, Taluk Board, Dindigul, h reference to the maintenance of the Bodinaik Ghât Road. Mr. Knight undertook the ma nance for the current year. *Proposed* by Davidson that a cess of 4 annas per acre be l the current year to pay the deficit on last y upkeep of the Devikulam to Mettu road. *Seconded* by Mr. Sc and *carried*.

R. and C., 206 of '98
18-3-98

It was resolved that the Honorary Secretary should continu correspondence with reference to the Pallapallyam-Chinnaar roa

Read letter from the Dewan of Travancore stating that Highness the Maha Rajah has been pleased to sanction an a maintenance grant of Rs.40 per mile for the whole distance of 21 of the path from Munaar to Devikulam and on to the Bodinaik mettu with effect from the beginning of 1073.

A vote of thanks to His Highness was recorded.

Insanitary Condition of Bodinaikanur.—*Proposed* by Davidson that this Association deplores the continued neglect o sanitary arrangements at Bodinaikanur by the responsible autho and strongly urges on Government the necessity of issuing o that immediate steps be taken for cleaning the town to preven spread of cholera which has recently broken out there. *Seco* by Mr. Murdoch and *carried*.

Dilatoriness of the Police.—*Read* letter from the Superinte of the Travancore Police giving cover to co instructions to the Assistant Superintende Police, Kottayam, with reference to the exec of certain warrants. *Resolved* that, as instructions do not seem to have had any effect, Mr. Sharp send a reliable person at the cost of the Association to accom the warrants and see them duly executed.

No. 212
30-3-98

Bodinaikanur Rest House.—*Proposed* by Baron J. vonRose that a sub-committee consisting of the Chairman and Hon Secretary, with Messrs. H. M. Knight, R. Hedge, and F. W. Sc be formed to consider the question of the new rest-house.

Telegraphs.—*Proposed* by Mr. Knight that the telegraph at Devikulam not yet having been opened, the following telegra sent to the Director-General of Telegraphs that "This As tion respectfully begs to bring to your notice that the telegraph at Devikulam has not yet been opened, although all is ready. I venience caused thereby very great." *Seconded* by Mr. W Martin and *carried*.

Artisans.—A resolution was passed that artisans leaving during working hours for the purpose of taking meals sha obliged to make good the time so occupied by working afte evening bell sounds.

The meeting then closed with a vote of thanks to the Chairm

A. H. SHARP,
Honorary Secreta

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co.'s Weekly Coffee Report (May 27, 1898) sa

Public Sales were only held on Tuesday this week in consequence Whitsuntide holidays and will not be resumed till Thursday, 2nd Ju

About 1,500 bags East India were catalogued and met a steady de previous values being well maintained.

A quieter tone prevailed in Central American descriptions and were rather irregular and in some cases slightly easier.

The Terme Market has again been quiet with very little business p and quotations are practically unchanged since our last.

srs. Wm. Jas. and Hy. Thompson's Report of the Colonial Markets for eek ending May 25th, 1898, says :—Bank rate 4°/₀. Bombay Exchange at 1s. 3 3/32d. Brazil Exchange 6¼d. Rupee paper 3½°/₀ 62⅛. Silver per oz.

market has been steady throughout the past week, and prices shew nge; the demand at auction continues very steady for almost all Brazil markets are dull.

y receipts averaged 7,400 bags in Rio and 6,500 bags in Santos.

ures: A quiet, tone has prevailed, prices shewing little alteration, Good average Santos in Havre, September delivery, fcs. 36,25, in urg pf. 30½, and No. 7 low ordinary Rio in New York $5.65.

— „ Java.
} Total 55,461 packages were offered in public auction this week.

The figures given below would at first sight appear to indicate a check in the consumption of British-grown Tea in North America; but they do not warrant such a supposition, because, as mentioned in our circular of the 26th March, 1897, the heavy import during the first quarter of that year was mainly caused by the fear of an alteration in the Tea Duty.

Almost all the increase which then occurred in Indian Tea was lost during the remaining three quarters, the total import for the year being 5,663,244 lbs., against 5,258,773 in 1896; the quantity of Ceylon Tea was 5,698,596 lbs., in 1897, and 4,364,510 lbs., in 1896, the increase in 1897 being mainly contributed during the first quarter.

Indian and Ceylon Tea taken in North America from 1st January to 31st March.

BSCRIPTION.—Advance Rates: Yearly, Fifteen Rupees; Half-yearly Rupees; Quarterly, Five Rupees, and Monthly, Two Rupees, including ge. Single Copies, Eight Annas.

DVERTISEMENTS.—From the 1st October, 1897, the charge for dvertisements will be: 4 as. per line for the first, 3 as. for the second, as. for the third and succeeding insertions. Five-line advertisements Subscribers will be inserted for three issues for one rupee; non-Subrs will be charged two rupees.

OMESTIC OCCURRENCE.—The fee for inserting a domestic rence will be *One Rupee* for each insertion, payable in advance.

3.—Remittances should be sent to the Manager, "Planting Opinion," Second Line Beach, Madras.

IMPORTANT NOTICE.

ne Business Offices of this paper having now been ved to Madras, all remittances should be made pay- to the Manager of *Planting Opinion*, 11 and 12, nd Line Beach, Madras, who will also attend to all rtisements, &c.

tters to the Editor should be addressed to Coonoor, ual.

SEASON REPORTS.

TO OUR SEASON REPORTERS.

Please post your next reports to reach Madras on Friday, the 1st July, 1898.

Season Reports should be sent to the Printers, Messrs. Addison & Co., direct, and not to *Planting Opinion* Office.

Mysore.

Belur, 17*th June*.—Failure has been "awful" here and in Belur and Munzerabad, so we are in for another bad year. One place is over 400 acres, and where a man saw the blossom in April and estimated 60 tons, quite one-half has gone! Borer also is worse this year. There are dozens of small estates for sale.

Coorg.

Polli Betta, 22*nd June*.—*Weather*.—About 1·50 inches rain on 16th. Heavy again on Saturday, 18th. Dropped again to 70·50 cents. "Break" on since yesterday, only 10 cents rain. *Crop*.—Light rain and break good for small berries. *Labour*.—New labour dribbling in. *Works*.—As previously reported, except that a beginning has been made with planting. *General Health*.—Fair. Paddyfield cultivation commenced. Grains and gram especially dear.

Kadur.

Balur, 20*th June*.—*Weather*.—The S.-W. monsoon set in on the 6th, and has been doing fairly well, with an average of 3 inches a day. Very high winds, which has brought down many trees. *Crops*.—Estimates on blossom greatly reduced. Owing to the long drought, "failure" is general all over the district. Borer has made its appearance on many estates. After the very fine promise of a "bumper" crop, it is disheartening, and we have still another bad year. *Labour*.—Some estates well supplied for time of the year. Coolies from below ghaut are beginning to make an appearance in larger numbers. *General Health*.—Fever still prevalent, but on the whole health fairly good. *Interesting Items*.—A large landslip occurred on the Bhoon ghaut on the 12th, which will stop all traffic for some days. Thanks to Mr. Rice (our Engineer), the débris is being cleared rapidly. A murder took place on the Merthikhan estate, when the maistry did away with his wife and two children. Murders have been frequent of late, and it is to be hoped the Police in this case will bring about a conviction.

Nilgiris.

COONOOR, 22*nd June.—Weather.*—Though the high winds have ceased, the skies are still very cloudy, but there is no rain yet. The need of more rain at this time is getting a little urgent. *Crops.*—Coffee has set splendidly, but with the effects of the failure of last year's N.-E. monsoon still apparent, more moisture is wanted to prevent the young berries dropping off. Tea wants more rain badly and crops, in spite of the late favourable weather, are fearfully behindhand all over the Coonoor district. *Leaf-disease.*—Bug, black and brown (latter is miscalled "green"), is showing up rather badly again this year on coffee in some parts. *General Health.*—General health still indifferent. *Interesting Items.*—I hear that our famous railway will have a good deal of difficulty yet in opening a through service to Coonoor this year. Trains, of *sorts*, are up to Burliar, but the difficulty is in the engines not being powerful enough to push up a full train.

NELLAKOTTA, 21*st June.—Weather.*—The monsoon broke here on the afternoon of the 6th instant, since which date I have registered 15·58 inches, or an average daily fall of a little over an inch. We have had no big burst, I am glad to say; but steady continuous rain, spread over day and night. Heaviest fall in any 24 hours 1·94. Wash in consequence has been conspicuous by its absence, and the wind has been very light. Altogether a model monsoon. *Crops.*—Berries swelling fast. The majority of estates have excellent crops: perhaps not quite as good as the blossom promised, but still excellent. The tote next to mine has a regular bumper. On a few estates, I hear, crop has failed. *Plant-diseases.*—Coffee, both old and young, in splendid heart. I have seen a speck or two of leaf disease, but nothing to speak about. I trust we may get off as lightly in respect of this pest as we did last year. Borer rather bad in patches. *Health.*—Colds prevalent. *Labour.*—Kanarese, as usual, late in coming in.

NOTES.

The Florida Velvet Bean.

All planters who have followed the interesting developments of the "legume cult" will be interested in Captain Wilson's description of the Florida Velvet Bean, which we publish elsewhere. It is good for shade, for forage, for manure, and for mulch. The Nilgiri A.H. Society might do well to import some of this seed for experiment from John Shaw and Sons, Great Maze Pond, Borough.

Vines *vs.* Coffee.

In the hope of making up the loss Brazil has sustained through the fall in the value of coffee, Dr. Barrets, a well-known agriculturist, has long been urging the cultivation of the grape, 600 varieties of which from all parts of the world he has been experimenting with upon his own estate in the San Paolo province. At a recent exhibition he had on view 300 varieties, and in most cases the products were superior to those of the parent country, both with respect to table fruit and that more suitable to the wine-press. Dr. Barrets evidently believes it better to get a new steed than to try flogging one lacking in quality.

The Currency Question.

The I. T. C. did not tackle this question with much zeal or zest, but it seems to have formulated an opinion at last. According to a telegram published in the *Madras Times* of 22nd instant:—

The General Committee of the Indian Tea Association have adopted the following resolutions:—That a gold standard is not needed in India, even if it be practicable to establish it; that the cost of establishing it (with or without gold currency) is prohibitive; and that an undue proportion of such cost will fall upon th growers; that, in the opinion of the Committee, the Indian Cur Committee should be directed to enquire into the question of h re-open the mints to the free coinage of silver with the least venience to the trade of the country.

Tea-pruning extraordinary.

An Upper India planter, "18 hailing, we believe, from the par larly distressed district of C Nagpore, has been giving Ceylon planters some extra nary ideas of his on pruning. To put it briefly, he holds by his improved method, an average estate should tur 1,600lbs. of made tea per acre! As the Indian and C averages are respectively 400 and 300 pounds per acre absurdity of the idea is patent. Friend "1874" a ye two ago was a very frequent and voluminous contribut planting periodicals, and from what we remember o quality of his writings, he seems to be now quite kee up to his old reputation.

A Correction.

We have had frequent occ to print extracts from that interesting journal, *Indian Gardening*, but much r that in a late issue we should have failed to acknowl the source of a report on the Government Gardens o North-West Provinces (which the printer's devil quot coming from the *Indian Government*) and an article o waste of fruit seeds. We publish this correction wi the more readiness because we have ourselves so frequ suffered the same annoyance from the hands of journals. Another extract or two will be found in this from *Indian Gardening*, to which we wish long life a long list of extractable articles. May its pages bro and its subscribers increase.

Ceylon tea-extensions.

In October 1895 the area of under tea in Ceylon was 30 acres, a large enough quantity in sooth. Yet in th two years planting was pushed on so rapidly that the pr area is close upon 370,000 acres, a huge increase. rally, the prospects of a permanently high exchange certainty of prices falling even lower than they now are practically stopped further extensions, as is the case in U India. The moral of these figures, according to the *C Observer*, is that North and South India should both gently refrain from planting up any more tea.

Unless the present conditions alter a great deal fo better, it is certain that a yearly increasing proporti poor tea land must be annually abandoned.

Mysore notes.

A Balur correspondent, writi the 15th instant, wishes we write something about the inefficiency of the local p On receipt of detailed notes we shall be glad to do so. writes: "You know that they (coolies from South Ca dug up McMaster's grave at Sumpsi in hopes of ge treasure, and the police never took the trouble to fin who did it. This grave-opening has been done once b in Koppa, where General Leslie's body was exhumed coolies, led by the cook, dug the grave open and were l by the Amildar for want of evidence. There has been a landslip on the Bhoon ghaut, seven miles from Kotag which has completely stopped all traffic from Mang Mr. Rice, the Engineer, is on the spot, and, working with 60 coolies, hopes to open the road in a

mite has been telegraphed for, as large rocks have come from the 'Jamkull' hill."

In the proceedings of the Coorg P.A. Annual General Meeting held e 31st May, which we publish in full elsewhere, will ınd many points of interest. It is satisfactory to hat though last year's crops, say 3,000 tons, were not ge as in 1895-96 (3,650 tons), yet they were consider- above those of 1896-97 (1,593 tons). Prospects for ear are considerably brighter, we are glad to see. interest is being felt in the opening of the first tea of any size in Coorg. It seems a pity, though, that er departure than tea was not tried instead, as pros- are the reverse of promising just now for tea gene- It is a pleasure to note that the importance of ving the local strains of coffee is at last being recog- This is a point on which we have dwelt times ıt number. The reputed area of coffee is now esti- at 109,385 acres, an apparent increase—due to te survey—of nearly 25,000 acres. One-third is by Europeans and the remainder by Natives. In- l, however, in the native coffee are large acres of oned cultivation, so that perfectly accurate statistics till to be prepared. Coffee assessment brought in 1½ an increase of 18,000 odd rupees over last year. disastrous effects of the restricted currency and high nge are forcibly dwelt on, and the utmost economy is to keep the industry on a profitable basis.

---

r to planters.

In his issue of the 3rd instant, the Editor of the *Produce World* draws tention of his readers to his offer to procure for rs and others specimens of plants, seeds, &c. We so add, writes our contemporary, that when any of aders or their friends come across products, especially l products, which they think may become commercial odities, we shall be glad to place at their disposal all sources for ascertaining not only their utility, but e chances and means of developing them and making rofitable. In several instances we have been enabled a remunerative market for previously little-known s, while we have frequent enquiries for information ning new products, and despatch specimen plants eds to all parts of the world by nearly every mail. We request, however, as there is occasionally difficulty aining some descriptions of plants and seeds, that our pondents should forward their enquiries as long before ctually required them as possible, in order to avoid g seasons and having goods rendered worthless on . All specimens are despatched by the earliest unity, but, while we do our utmost to meet require- we cannot guarantee the safe arrival of any special y under present shipping laws.

may add that the paper, being run by Messrs. John n & Co., is particularly capable of affording very le assistance in the manner indicated.

---

oranges in on.

Some four to five years ago several consignments of oranges, says the *Produce World*, were sent to London Central India, and arriving out of the usual season there, many realised as high as threepence each. Unfortunately, the consignment had to be shipped as ordinary cargo, and even then there was difficulty in inducing shipping companies to accept freight, consequently much of the fruit was bad on arrival. The writer of notes on "Indian Fields and Farmers" in the *Madras Times* had some interesting remarks lately on this very subject. He suggested that the difficulties inseparable from the initiation of any trade might well be met by Government. Of course planters would in time reap a substantial part of the benefits of the fruit trade, but it is the Indian ryot who will for many years be most keenly interested in the matter.

It is interesting to note here what the rates of freight are for fruit from the Cape and from Australia. From the former colony a ton of fruit is charged £3-10*s.*, while from Australia, which is double the distance, only £4-5*s.* are charged to London. To intending shippers it will be useful to bear in mind, in the words of the Cape of Good Hope *Agricultural Assistant*, that "no one knows better than the Covent Garden Salesman that, to a large extent, it is the box that sells the goods, and the first fruit in the world would be heavily discounted by being presented in shabby second-hand surroundings.

Mr. Kelway Bamber.

This gentleman, so well-known to all tea-planters of India and Ceylon from his noteworthy book on tea, has now returned to the East to see if his services cannot be of further use in these depressed times. Undoubtedly the problem which calls most urgently for solution is the question of the scientific manufacture of tea. Not that we incline to the belief that chemistry in the factory alone will be of great assistance. Its work lies afield as well; strength, flavour and pungency must be traced from cup to factory, from factory to bush, from bush to soil, and thence back again. Mr. Bamber was lately in Ceylon and has been giving his opinions, very guardedly, on the alleged deterioration of the local tea to the *Ceylon Times*. "Absolute deterioration in the quality of tea may arise, apparently, from gradually increasing poverty of the soil, or from methods of manufacture unsuited to bring out the best qualities of the tea. And we are glad to find that Mr. Bamber does not believe that the most careful analysis, or series of analyses, will suffice to give us much valuable information on the subject we are trying to elucidate. Without practical experiment with the mechanical processes of tea manufacture, carried on hand in hand with scientific

MANAGER, ARIENKOW ESTATE,
Shencottah.

tests, little can, in Mr. Bamber's opinion, be done, and he desires to work with men who will come with him and personally go through all the processes in order that the work may be carried on in a practical, as well as in a scientific, way. Such work as that is certain to lead to good result, and we can only hope that the Thirty Committee will see their way to engage Mr. Bamber's services in the same way as was done in India, where a substantial retaining fee was given him by the Tea Association and a certain definite scale of charges was drawn up which he was authorised to charge to different estates for analyses of soils, and teas, and work in the factory. Such a system as this will allow of Mr. Bamber's services being secured at a minimum cost to all who wish to consult him, and to take advantage of the presence amongst us of one who is quite at the head of his profession at home, and has already given many years' study to the chemistry and scientific manufacture of tea."

London Market.

Coffee.—The position of the market is thus shown by the *Produce Markets Review* of the 28th ultimo :—

LONDON COFFEE RETURNS.

Indian Teas.—The quantity offered has been smaller but sufficient to meet the somewhat slow demand. Prices have been steady for the lower descriptions, which formed the bulk of the supply, and a smaller quantity was withdrawn than has lately been the case. Teas for price meet with a good inquiry, but the supply under 5¼*d.* with useful liquor is in a very limited compass. Medium sorts have scarcely changed in value, the bulk of the offerings showing but moderate quality in cup and comparing unfavourably with similar grades offered some time ago; consequently the trade have not been eager buyers excepting for actual requirements. The fine and finest kinds continue extremely scarce, and the few parcels brought forward were keenly bid for, in most cases at enhanced rates. The reports of the new crop are on the whole favourable, and it is generally expected that the quality of the teas from most districts will show an improvement on those of last year. The estimated outturn is put at 158,500,000 lbs., of which 140,500,000 lbs. will probably be available for this market, against an actual outturn of 148,250,000 lbs. last season, the latter being about 8,000,000 lbs. below the early estimate, and 133,750,000 lbs. were sent here. Public sales were resumed in Calcutta on the 20th inst., when 8,000 packages were offered, and the quality of some of the teas is reported to be good, for which firm prices were paid, but the common kinds sold at easy rates. At the public sales 16,307 packages were brought forward, of which 13,756 were sold. The next auction will not be held until M day, 6th June.

Formosa camphor.

According to a report of I Consul at Tainan, writes an change, the camphor export for the year 1896 was 8 boxes, which is a decrease of 2,144 boxes from the ex of preceding year, and of 4,156 from that of 1894. trade from January to April was most remunerative, o to the high prices ruling in Hong Kong. Then the Ja ese authorities, by the issue of regulations affecting production and sale of camphor, and by the arbitrary a of foreign compradores and the confiscation of their phor in the interior, so seriously interfered with the tions existing between foreigners, their compradores the camphor workers, that by June business was pr cally brought to a standstill. Repeated remonstra from the Consular body had the effect of partly allevi the situation, but before confidence was fully restor rebellion broke out in and around the camphor dist and put a stop for several months to all further busi During this time most of the camphor stills, which we erected by foreign capital, were deserted by the cam workers, to whom advances had been made for the chase of camphor trees and the manufacture of cam for the account of foreigners, the latter thus suff heavy losses. When order was somewhat restored, the large quantities of camphor which had been lying up country for several months could be transported t coast, prices in Hong Kong had fallen 70 per cent., did not improve for the remainder of the year.

The regulations above referred to, and others s quently issued, if allowed to remain in force, will the effect of gradually excluding foreigners from a ness which they originated, and of which they before the Japanese occupation of the island, practica monopoly. Lately, however, the Japanese Govern have agreed that the camphor business is to be carrie by foreigners under the same conditions as formerly the new treaties come into force. It is to be presu therefore, that any Japanese regulations restrictive o trade will be put in abeyance this year, and that the officials will be instructed accordingly. There would be a prospect of the trade reviving and assuming proportions; but the outlook at present is not at al assuring.

LETTERS TO THE EDITOR.

RECIPE FOR LIME JUICE.

SIR,—The following will be found a good recipe for ma "lime juice" to keep. Squeeze the limes, strain the juic put it into a clean-lined saucepan. Bring the liquid t boiling point, put into bottles quite dry inside, but made h placing them in hot water or in the oven. Cork tightly new corks, then dip the ends of the bottles in melted res exclude all air, and keep in a dark dry place. The l should reach up to the corks.

To every pound of sugar add 12 fluid ounces of lime add a few drops of essence of lemon, and dissolve with th of heat, 1 oz. of the syrup to a tumbler of aërated water. very strongly recommend the fruit crystals which ma

t for annas 7 per packet, in lemon, raspberry, orange, ople and lime juice flavours and are so easy to make.
ce the contents of one bottle in a jug with 1 lb. loaf Pour over the whole one pint of boiling water. Stir till ved, when it is ready for use. Use a tablespoonful or two syrup to a tumbler of water.

A Planter's Wife.

TEMPERATURE OF TEA DRIERS.

AR SIR,—I see "Tea Drier" in your issue of 4th June has into the natural error of considering one substance hotter another, merely because it feels so, disregarding the fact most metals are much better conductors of heat than air; lone making the wire mesh feel much hotter to the touch the air surrounding it. In natural up-draft siroccos, the rrounding the trays, and also the trays themselves would ler than the air surrounding the thermometer (where it is ly fixed) being further from the source of heat.

a is liable to bake or burn at any temperature above f left sufficiently long.

e true theory of the burning of tea in dryers is that the erature of the roll while sufficiently wet rises very little 212° F., the vapourising point of water, but as the drying completion rises rapidly towards the temperature of the hot assing through it (say 240° to 306 F.), and if the dried tea t long enough, it will certainly burn in either of these eratures.

is is provided for in Messrs. Davidson's later type down s, and in their new Auto-Sirocco, in which the wet roll is cted immediately to the hot dry air, while the nearly ed tea passes through a much reduced temperature.

Heat.

GENERAL ARTICLES.

TEA PESTS AND BLIGHTS.

(*Continued from page* 250.)

Fertilisers. The interesting chapter under this heading has been supplied by David Hooper, Curator of the Indian Museum, Calcutta. Hooper achieved a substantial and well-deserved tation while in South India for the careful way he stigated economic questions presented him. Our ex- ations of finding a well-written and suggestive chapter not disappointed. Mr. Hooper holds to the full Watt's well-established theory that predisposing con- ns to disease in imperfect methods of cultivation call nvestigation more urgently than any so-called cures he diseases themselves. More especially with regard eficient or unsuitable food supplies.

is unavoidable that the chapter partakes closely of the re of the book itself, *i.e.*, is not authoritative, but only gestive. As an introduction it is worthy of praise. as with the rest of the book, much investigation and ful work is needed before planters can turn to it for rence. With special reference to the health of the tree, Hooper lays great stress on the important effect that ogen has in keeping off blights by maintaining the t in full vigour. Green manuring is advised wherever cticable, and some interesting matter relating to soil ification and the absorption of nitrogen by leguminous plants. In fact, the conclusion to which the whole chapter leads to is that sufficient nitrogen under ordinary favourable circumstances has an enormous effect in warding off the attacks of blights and other pests. We are given the formula of what may be called a normal manure for tea, that is, a complete manure. In most soils, some at least of the constituents would not be needed and, with soil analysis to guide one, should be omitted. The following is the formula:—

Mineral phosphate (containing 60% of tricalcic phosphate)	50	Lime ...	... 16
		Phos. Acid	... 14
Saltpetre (95%)	... 30	Potash ...	.. 13·3
		Nitrogen (in nitrate)	3·9
Ashes (of wood or plants)	... 20	Potash ...	... 2
		Phos. Acid	... 1
		Lime ...	... 1

A manure of this description, says Mr. Hooper, could be easily prepared in India. A natural phosphate of the above description is afforded by the deposits of nodules near Trichinopoly. If mineral phosphate is not procurable in Northern India, bone dust, an article which would supply additional nitrogen or ammonia, might be substituted. If more nitrogen is required, the ashes might be replaced by one of the many oil-cakes obtainable at a cheap rate wherever oil-seeds are cultivated and pressed.

Conclusion. In reviewing our previous notices on Tea Pests and Blights, we are led to the following conclusions. That, while some of the serious enemies of tea may be found even in perfectly healthy tea, in the majority of cases, the plant only suffers when it is in an unhealthy state. Unhealthy stock must give unhealthy progeny, and there is no doubt that in tea, as in coffee, an alarming proportion of the unhealthiness of the plant is due to heredity. There is only one way of combating this evil, *i.e.*, to gradually improve our seed-suppliers by the most careful selection and cultivation. That is a problem for the immediate future. Apart from the complex question of heredity, a great deal of the debility of the plant can be directly traced to faulty methods of pruning, cultivation, draining, manuring and plucking,—grave faults of both omission and commission. These faults can be remedied by an improved system of working, not necessarily entailing any additional expenditure. Cultivation, as we have pointed out in one of our preceding articles, is nothing more than keeping the pores of the surface and subsoil open to the influences of rain and air. It is intimately connected with subsoil drainage, for surface catch drains are apt to have most harmful effects, being based on an entirely erroneous principle. To keep his tea healthy, the planter must subsoil drain his land in the best manner he can. Subsequently, by cultivation frequent and deep enough to satisfy the conditions of the soil and climate, he must, aided by judicious manuring, not only keep up but increase the fertility of his soil. In pruning he should endeavour to form the shape of his bush at the earliest possible stage, beginning even in the nursery. For the earlier the desired shape is attained, the less shock there will be to the tree, and the less waste of its vital forces. When through age or neglect his plants no longer respond to a medium prune, let him cast aside his fears and stump them below the surface of the soil. All new shoots will be able to provide their own roots, and thus in time will form entirely new plants.

With his plants in a thoroughly healthy state, he will find that the need for insecticides will be almost infinitesimal. But he should not neglect the attacks of blights, however well his tea is growing. It is a sign that all is not well. It must first of all be rigorously suppressed by powerful insecticides, or even fire if necessary. Next comes the question of discovering and correcting the causes of the attack. Eternal vigilance, great powers of observation and a ready intellect are needed to successfully wage the war against pests and blights.

PARA AND AMAZONIAN RUBBER.

IT is stated in a Foreign Office report from Her Majesty's Consul at Para that the total amount of Amazonian rubber exported from Para, Manaos, Bolivia, and Peru during the twelve months ended June 30, 1897, was 22,216 tons, of which 12,368 tons were sent to Europe and 9,848 to the United States. The Amazonian crop during the same period amounted to 22,315 tons, of which 9,100 tons belonged to the State of Para. The amount of Amazonian rubber exported during the year ended Dec. 31,1896, was 21,597 tons, of which 12,542 tons were sent to Europe (10,637 to the United Kingdom and 1,905 to France) and 9,055 to the United States, while the amount of Amazonian rubber exported in 1897 (Jan. 1 to Dec. 15) was 20,554 tons, of which only 9,726 tons went to Europe and 10,828 tons to the United States.

The value of the rubber exports from Para during the year 1896-97 was £1,977,596, and the duties collected on this value amounted to £415,295.

All the trade between States watered by the Amazon (*i.e.*, Para, Amazonas, Peru, and Bolivia) and the United States is transported in British bottoms; and all the rubber purchased by the United States is paid for through British banks, of which there are three established in Para. A British company—the Amazon Steam Navigation Company of London—possess 35 steamers for the navigation of the river Amazon. Over 100 river steamers belong to Para. Most of them were made in England, and merchants in Para, Manaos, and Iquitos are continually purchasing others from the same source. Purchases have been made also in the United States, France, and Germany, but the British article is found to be superior

Rubber of the best quality is produced throughout the continent watered by the Amazon between Para and the Andes mountains of Peru, and the majority of authorities on the subject are of opinion that there is absolutely no fear for the exhaustion of the supply of rubber in the Amazonian States. Distance and rapids are not insurmountable obstacles, for in some cases this produce is transported as much as 6,000 miles before it reaches Para; and, when rapids impede the way, canoes and their cargoes are hoisted out of the water and rolled along the banks, sometimes for several miles, until navigable water is reached. This causes much delay and additional expense, but it is found in the end that distance and prolonged transportation have improved the rubber, so that when it arrives at its destination it sells for higher prices than that collected nearer the mouth of the river.—*Journal of the Society of Arts.*

COOL DRINKS.

"G. C. M." writes to the *Pioneer*:—I have recently been making a number of experiments regarding cooling mixtures with the following results:—The most effective mixture for its cost is, one part of saltpetre (naushadas) and three parts of sal-ammoniac (shora). Pound the crystals fairly fine, mix them together, and add one part (by measure) of the mixture to two parts (by measure) of water. For cooling bottles I use a number of earthenware *chulas*, packed round with sand, in a wooden box. Each *chula* is just big enough to hold a bottle, with about half-an-inch space all round. For measuring I use an empty tobacco tin. About four or five tins full of water suffices, into which I put two tins full of the mixed salts. The mixture should be well stirred first, then the bottle is put in, and is occasionally taken out and well shaken. The liquid inside the bottle reaches its coldest point in from half to three-quarters of an hour. I find I use about half a seer of the salts for each bottle. As the price of the mixture is about six annas a seer, this would be expensive, were it not for the fact that the whole of the salts can be recovered by evaporating the "brine" in shallow pans. While in camp I take with me two large, strongly made block tin cans, each holding about 5 gallons in which I put the brine, to be evaporated when I return to headquarters. For evaporating pans I am at present using trays made of tin placed in wooden trays. I find, however, that the tins get rusty after a while and make the salts black. Shallow earthenware pans would be better. In the hot weather about one quarter of an inch to half an inch depth can be evaporated during the day. During the rains this depth will have to be reduced. The brine should be carefully strained before being put in the pans. It will be found when cooling a bottle that the heat from the bottle soon "warms up" the surrounding brine. If after a while the bottle is removed and put into a fresh solution, several degrees of "cooling" will be gained. The greatest reduction of temperature I have reached with this mixture is from 86° to 61°, but this was *without* a bottle in the *chula*. With a bottle in the *chula* the greatest reduction of temperature of the brine was from 80° to 63° and of the liquid inside the bottle from 80° to 68°, this point being reached after 35 minutes. There is no advantage to be gained by increasing the proportion of salts to water beyond 1 to 2. It is better to cool the bottle twice, if it is wanted extra cold, using *fresh* water for the second cooling. Of course the coldest water obtainable should be used, and the bottles should first be cooled, either in a swinging basket, or in a *gumlah* placed behind a *kus-kus tatti*, or in any other convenient way. As a little carelessness may result in the loss of a lot of salts, I find it advisable to give the servants a small sum per seer of salts recovered.

THE FLORIDA VELVET BEAN.

THE following letter has been addressed by Captain E. A. Wilson, Orlando, Florida, to the *Spectator*:—

TO THE EDITOR OF THE "SPECTATOR."

SIR,—I send you herewith a sample of the new Florida product,—the wonderful velvet bean. Up to two years ago it was grown here in a limited way, mainly as a trellis shade, but afterwards it became recognised as invaluable for all kinds of stock as a forage, and a phenomenal fertiliser for orange and other fruit trees, and for the soil as well, until it is now grown in large quantities. There is nothing yet discovered that is, all in all, so valuable a crop as this for farmers to raise. It being an air plant, it would do well in most any kind of soil, in any of the States, north or south, that will grow corn, and no fertilising is necessary. The forage—the foliage, and vine—coming from this bean is a marvel and a wonder. Planting in rows 4ft. apart will produce a solid mass of vine and foliage, up to your waist in height, covering the ground completely, and yielding leaf, vine, and fruit, aggregating four to five tons to the acre, and of dry beans twenty to thirty bushels. Beside the vine being a valuable fertiliser, forage, mulch, and shade, the question will be asked, "Is it also prolific in fruit?" The answer is "Yes, emphatically so." From the hill the vines run out in all directions, like the water melon, 10ft. to 20ft. It commences to fruit at the hill in clusters like the raisin grape, thence along the entire length of the vines at intervals of 10in. to 20in. pods in clusters of from two to twenty appear. Therefore the fruitage must be immense. For twenty years this bean has had a home in Florida, and has been known among the people as "the climber." In good rich soil it will climb 50ft. to 60ft., blooming and fruiting all the way up,—a most beautiful and lovely sight to look upon. To drill an acre will take sixteen quarts of seed; to plant an acre in rows 4ft. apart each way about twelve quarts. In good soil this acre will produce four to five tons of green forage, and fifteen to seventeen hundred pounds of beans. I speak from practical knowledge, as I have recently harvested nineteen acres of as fine a crop as ever grew.

Plant seed in spring the same time as you do corn, and cultivate and treat in same way, until vine begins to fill the row, then lay by for the season. When bean is ripe in the fall pick it, then turn mass of dry leaf and vine under for fertiliser, and from this your soil is immensely benefited. It is a good idea to drill or plant corn right in with bean seed as a partial support to vine, to keep pods off the ground. You can turn stock into bean field if you wish, or cut vines up at hill and carry out to stock, latter being advisable. If

planted in orange grove or orchard, keep 5ft. or more away from trees, as vine is a rampart grower and climber, and will cause you bother. Experience has shown that it is better to drill than to plant in hills, as by drilling you get a better stand on the ground, and that is important. The beans ground up, hulls and all make a fine fertiliser for pineapple, orange and other fruit trees, as well as for all vegetable growth. Stock of all kinds like it, as well as the green forage early in the season, and all do specially well on it. Every living thing on the farm will eat the green forage and dry bean with greediness. The dry bean is also fit for table use. The question is often asked if this newcomer—the Florida velvet bean—will do well in any other section of our country except Florida. I answer by saying there is no earthly reason why it will not, as it is not tropical, and will do well wherever corn will grow. After having made a thorough test of it, I have come to the conclusion that, as a fertiliser, forage feed, mulch, shade, a prolific bearer of fruft, an up-builder of the soil, this bean has no rival. As a porch and trellis shade, with its beautiful dark-green foliage, and its long, pendant, down-hanging purple bloom, it is truly lovely. The analysis of this bean shows:— Nitrogen, 54 per cent.; crude protein, 19; fat, 6; fibre, 8; moisture, 12.

Orlando, Florida. Captain E. A. Wilson.

P.S.—If you desire to say, for the benefit and information of your readers, that this seed may be obtained in your city of John Shaw and Sons, 5, Great Maze Pond, Borough, you are at liberty to do so.—*The Produce World.*

WHY NOT A BULB FARM AT COONOOR?

From what I had seen of Coonoor, in the Neilgherries, writes Dr. Bonavia to *Indian Gardening*, I should say that a bulb farm there would be a great success. I saw hedges of Heliotrope; Camellias growing in the open; Richardias in the water courses, and many other things which prove that the climate and soil would be suitable to a bulb farm.

There is one curious phenomenon connected with commercial bulbs. In Japan there is a company which grows bulbs for the European market, mainly lily bulbs. I have purchased enormous ones of *Lilium auratum* at an astonishingly low price, and the importer had to make some profit out of them. But the curious thing is that Japanese lily bulbs go to England, and then back to India! Why cannot a trade be started of such things from Japan to India *direct*, instead of getting them from England by a sort of "reflex" action?

Lilies are among the hardiest things. Here, in England, they can be planted, and never again touched. Year after year they reappear above ground at the proper season, and flower in due course. There are many parts of India where they could be similarly grown. In all the hill stations, and probably in the plains also, they would find a suitable home. There is nothing finer in the way of flowers than lilies of about a hundred varieties.

Well, a bulb farm in Coonoor ought to prove a success, not only horticulturally, but also financially. There are so many improved bulbs of various kinds which might be grown in such a charming climate as that of Coonoor. To mention a few. There are all the splendid Narcissi, of which I have recently been enjoying a fine exhibition at the meeting of the Royal Horticultural Society. Some of them are astonishingly beautiful, such as the "Empress," the "Emperor," "Sir Watkin," the "Glory of Leyden," "Maximus" and many others. But that is not all, for many other splendours are on the horizon, and in a short time these new Narcissi will come into commerce.

Why should not Hyacinth bulbs be grown at Coonoor on a commercial scale, just as in Holland? They seed profusely, and new varieties can be raised from seeds. The fine named sorts can be raised from offsets.

Then there are the famous Amaryllis bulbs of Lucknow (Hippeastrums). Mr. Ridley, of the Government Horticultural Garden of Lucknow, could supply a cartload of these astonishingly beautiful things such as no lilies could match for splendour of colour. They are as easily grown as onions. Natives would never initiate such a bulb farm anywhere: the undertaking must be done by a European.

Many a retired officer passes the rest of his days on the Neilgherries; and let me tell you that he must be an unwise person, not to say a fool, who would care to exchange the climate and beauties of the Neilgherries for the nonsensialities of the London theatres and music halls, with a good seasoning of thick yellow fogs!

Well, a retired officer with a turn for horticulture and with a power of observation, and the knack of profiting by what he observes, might do worse than start a bulb farm in Coonoor. From small beginnings the creation of the plants and animals of this world has come about; and so may a bulb farm in Coonoor be created from small beginnings. Usually a retired officer in an Indian hill station ends his days twirling his fingers and reading papers at his club—a very foolish occupation for the end of one's days. Here is an opening for some enterprising retired officer, who has still some life in him. If he succeeded in making a good thing of this opening and fascinating occupation, he might bequeath a fine property and business to his sons, if he had any. Every one with capital there rushes into *tea*, to spoil his own market, and that of every one else. Here is a novel thing. If it succeeded, the whole of India might be supplied with bulbs, besides Ceylon, Burma, the Straits, and many other places.

Many of these fascinating bulbs can be cultivated, and new ones raised as easily as common onions. The great fascination of modern horticulture is the crossing of species and varieties for the production of *new* creations, which no man's eye had ever seen before.

I think the idea of a bulb farm in Coonoor offers not only a charming out-door occupation, but probaly may turn out to be also a profitable occupation. Knowledge of the plants—which may be *learnt*—perseverance, and a little capital, are the only requisites to begin with, in addition to the enchanting climate and soil of Coonoor.

NEGLECTED INDIAN PRODUCTS.

An interesting article has recently appeared in the Calcutta weekly *Capital* on the concentration of industries in British India and the openings for capital which present themselves in that country.

Speaking first of the production of lac, the writer is of opinion that a well-managed farm for the purpose affords as good and safe an investment for capital as any the country can offer. It is said to have failed when attempted in Cachar, but that was simply from the person who undertook the business being unacquainted with the habits of the insect, and placing his nucleus out in the full blaze of the sun, whereas it is only found in the densest forest undergrowth.

Again, take the item of beeswax. The southern face of the mid-mountain range teems with hives; and in many villages artificial ones may be seen. Yet no European has turned his attention to the important industry of apiculture, though no more eligible site than the orange groves could be had, the blossoms of that fruit in March and April affording perhaps the most suitable food for the many million of insects that are encountered. Although there is but little doing in the wholesale trade, the price of the comb, as brought in by the people, has risen within the last decade from 2a to 6a per seer, and allowing 25 per cent. for honey and impurities, there results in a difference between the rs 20 for the 70 seers that will make up the cwt., and £7 to £8 the latest quotation in London for Zanzibar wax which the Assam article resembles.

As to the trade in cocoons, it has of late been permitted to fall entirely into the hands of natives, and yet so plentiful are cocoons in the jungles that the bringing up of the worms in a domestic manner admits of no difficulty. In purchasing these from the hillmen one has to undergo considerable trouble and annoyance, for no amount of persuasion or invective will induce them to keep the different varieties separate, though latterly the Meekies seem inclined to come to reason in this particular, but the other tribes argue that silk is silk, and will not or cannot understand why one cocoon is not as good as another. The consequence is that a good deal of trouble has to be spent upon sorting, which would not be the case were each variety brought up on plants they affect and kept separate; and the laying down of such area as might be required in castor, soom slips, and other plants would prove a very trifling matter, while the necessary cultivation would be limited to merely cutting down the weeds now and again.

Of fibres, generally, so much has been written, that to enter into

details concerning them would be superfluous; all the slopes of the hills furnish the aloes variety in abundance, while there are long stretches in the plains available for the grass. The oil-producing plants such as castor, chalmoogra, and croton are equally valuable, whether considered solely as such, or for their cake. It is becoming more and more apparent that the older tea-plantations need renovation of soil; not that there is any falling off in yield, but in quality.

With the exception of mustard and linseed, the oil trade in N.E. India has been unaccountably neglected. Yet in no part of the country do the plants mentioned above grow more luxuriantly or yield more abundantly, and were local mills established to which the seed could be passed in a fresh condition, the oil obtained would be of better quality than that expressed from seed sent down to town which not only loses in weight, but is subjected to the risk of sweating on the journey. Public attention has been so fixed upon tea, that other important matters have remained unheeded; and the day may come when planters will become aware that only the finer sorts of tea will find a remunerative market. Hence it is well that other industries should be taken in hand.

There are so many jungle products that could be brought into plantations and concentrated that it would take up too much space to enumerate them. But ginger, turmeric, or anise could be raised in any quantity. Attention is continually being drawn to new uses to which Indian fruits can be put, and among others is that of plantain flour. This not long since formed an important industry in Jamaica, and an analysis showed it to contain certain properties as valuable as the infants and invalids' foods now turned out in such large quantities. Cassava flour again, so rich in starchy matter, ought not to be passed over.—*The Produce World.*

THE USES OF WOOD.

By FILIBERT ROTH,

Expert in Timber Physics, Division of Forestry, U. S. Department of Agriculture.

GENERAL REMARKS.

WOOD, like soil, air and water, has until recent times been one of those materials which man could obtain without effort beyond the mere taking. Hence, although it has become one of the most important, most generally used, and to our civilization most indispensable products of nature, our attitude toward its production has been one of indifference. Wood has been used so generally that a large amount of empirical knowledge regarding its properties has accumulated. This knowledge has sufficed for immediate purposes, and the need of a more intimate knowledge gained by investigation and experiment in regard to the properties and characteristics of wood has never become very apparent. Abundance and cheapness, together with ignorance of its true merits, have led to a most extravagant and often erroneous use of this product. We have witnessed with indifference, also, the useless destruction of enormous quantities of timber in the vague belief, characteristic of the times, that when the supply is gone some substitute will be found. That this belief is poorly founded is quite apparent, for while such substitution as, for instance, that of iron in ship, bridge, and track construction has taken place, and undoubtedly will continue and even increase in many directions, it has not prevented, even in countries like England, where wood is dear, an increased consumption per capita of population, while Germany, with all its well-managed forests, imports great quantities of large sized timber. Moreover, as we learn to know the properties of this material, we find that it is capable of many uses for which it was supposed the metals alone were fit; wood is to-day displacing the best qualities of steel even in such delicately balanced structures as the bicycle. That this return to wood in many of our manufactures will continue, in spite of the cheapness of iron and steel, there is not the slightest reason for doubt, and the importance of wood as a material of construction, to say nothing of its use as pulp, cellulose, and its derivatives, and its growing value as a fuel, will steadily increase and not decrease, as is so commonly assum and taught.

Before entering into the discussion of the uses of different kin of wood, and the reasons for their selection, it may be well to revi the principal useful qualities of this material, and to some exte compare it with its most natural substitutes.

WOOD AS COMPARED WITH IRON.

1. Wood is a natural product; iron the product of a costly, co plicated manufacture. Wood may be grown wherever man wishes use it; the manufacture of iron is practically confined to particu localities. The mines of both iron and coal are exhaustible; t forest, under proper management, produces for ever.

2. Wood is cheap; metals are dear. Even in the form of lumb and with the cost of long-distance transportation added, wood co the consumer in this country rarely more than 25 cents per cu foot, while iron in bars and sheets is worth at wholesale from $5 $10 per cubic foot.

3. Wood is soft; simple tools and small effort suffice to shape Iron is hard, any change of form, whether by casting, rolling, sawin cutting, planing, turning, filing, boring or grinding, requires mu labour, or else complicated and costly processes and equipments. the ease and rapidity with which wood can be shaped, reshaped, a combined in structures, it excels all other materials.

4. Wood cleaves or splits; metals do not. While this proper has its disadvantages, it is one that in some directions determin the usefulness of wood. It permits ready preparation for fenci and firewood, which latter use exceeds in bulk ten times the amou of iron and steel used in this country.

5. Wood is stronger than is usually supposed. In tensile streng (pull lengthwise or with the grain of the wood) a bar of hicko exceeds a similar bar of wrought iron of the same length and weigh and it even surpasses steel under the same conditions.

Similarly, a select block of hickory or of longleaf pine sustains greater weight in compression endwise (parallel to the grain of t wood) than a block of wrought iron of the same height and weigh and nearly approaches cast iron in this respect.

6. Wood is very elastic and resists bending to a marked degre and though the modulus of elasticity of iron as ordinarily stat appears 10 to 15 times as great as that of good ash of longleaf pi yet a square 10-foot bar of the latter wood requires 6 to 8 times great a load to bend it by one inch as a similar bar of iron of t same length and weight. Moreover, wood endures a far great distortion than the metals without receiving a "set" or permane injury. It does not rust nor crystallize, but retains its quality, a being light, and therefore used in solid pieces, may be selected wi perfect assurance of avoiding "flaws" which are so dangerous in metals when used in small pieces combined to make a larger structu

7. Wood is light; iron and steel are heavy. The average weig of all wood used in this country does not exceed 31 pounds per cub foot; that of iron and steel is from 430 to 450 pounds per cubic fo This quality effects ease of handling and transportation; it permi the floating of most woods when green and of all when dry, a with its superior strength and stiffness results in a saving of mo than 75 per cent. in the weight of structures, frames, floors, furnitu etc.

8. Wood is a poor conductor of heat and electricity. Heated 150° F. or cooled below the freezing point of water, iron, steel, a other metals are painful to the touch, and even far within the limits metal objects are objectionable on account of their rea conductivity of heat. Wood, on the other hand, is entirely inoffe sive as long as its temperature remains within the above limits. T objections to metal dwellings on this account are experienced al in heavy-armoured ships, which, in spite of the excellence of oceanic climate, are notoriously uncomfortable and even injuri to health.

When exposed to heat, wood is ignited and destroyed by fi The inflammability and combustibility of wood at high temperatur though among its most valuable properties, are, at times, a drawba which metals do not share; for, while a beam of wood burn it retains its shape to the last, and the structure may stand and saved, while under the same circumstances metal beams twist o of shape and thereby occasion the fall of the entire structure. Th

behaviour of wood in conflagration has induced the best authorities, fire underwriters and others to recommend the use of wood in all large structures where the combustible contents of the rooms annul the value of fireproof metal construction.

If wood were a good conductor of electricity, its usefulness as a material of construction in our large cities would be much impaired, for it appears to be a very serious and constantly growing difficulty to protect life and property against this dangerous and yet so useful force.

9. Woods are normally inoffensive in smell and taste;liquors and wines of the most delicate flavours are kept in oaken casks for many years without suffering in quality. Chemical changes, often directly producing poison, prevent the use of cheap metals for these purposes.

10. Owing to their structure, all woods present varieties of characteristic aspects and possess no small degree of beauty. A plain surface of metal, of whatever kind, is monotonous, while one of wood, unless marred by paint, presents such a variety of unobtrusive figures that the eye never tires of seeing them. That this beauty is quite fully appreciated is best illustrated by the fact that pianos, sideboards, and other elegant furniture are not covered with sheet metal (as they might very cheaply and effectively be) and that the handsome floors of costly structures are neither painted nor carpeted.

11. Wood is easily and effectively united by the simple process of gluing, so that valuable combinations, whether for behaviour, strength, or beauty, are possible. A three-ply veneer board may not only be as pretty as, but also more serviceable than, a simple board of any one of the two or three kinds of wood of which it is composed, and a white-pine door with cherry or walnut veneer is not only fully as handsome as a walnut door, but it is far superior in its behaviour. Since all shrinking and warping is thereby practically prevented, iron and steel may be welded, most metals can be soldered, but none of these processes can be compared to gluing in effectiveness and ease of operation.

So far wood has been regarded only as a material of construction; but while this is perhaps the most important consideration, the use of wood as a substance which may be altered physically and chemically is far more important than is generally admitted.

12. The great mass of mankind is warmed and has its food cooked by wood fires. Even in this country to-day, in spite of the great competition of coal, three-fourths of all the houses and thousands of manufacturing establishments are supplied with heat from wood.

13. Wood is ground into pulp and made into paper and pulp boards with endless variety of application. Wood pulp made by chemical processes results in cellulose and its countless derivatives, which are capable of supplying almost anything, from a shirt collar to a car wheel.—*Tropical Agriculturist.*

SHEVAROY.

PROCEEDINGS of the monthly Committee Meeting of the Shevaroy Planters' Association, held in the Victoria Rooms, Yercaud, on Monday, the 6th June, 1898, at 1 P.M.

PRESENT.—Mr. S. M. Hight, Mr. Thurston Short, Rev. J. M. Kempf, Mr. C. G. Lechler (*Chairman*), Mr. R. Gompertz (*Honorary Secretary*).

1. Notice calling the meeting was taken as read.

2. *Read* letter from the Secretary, U.P.A.S.I., dated 5th ultimo, enclosing extract from a letter from the Chairman proposing that his expenses, when attending the Annual General Meeting, should be paid by the U.P.A.S.I., as well as Rs.10 per month to cover the expense of a clerk and postage.

The proposal was approved.

3. *Read* letter from Secretary, U.P.A.S.I., proposing that the Annual General Meeting should be held during the Bangalore races.

Not approved of.

4. *Read* letter from Honorary Secretary, South Mysore Planters' Association, proposing that the U.P.A.S.I. dinner be eaten on the 13th August; and that the meeting should open on the 15th idem.

Approved.

5. The following letters were read and recorded:—

Correspondence with the Accountant-General on the subject of supply bills.

Three Circulars from Secy., U.P.A.S.I., *re* Currency question.
One do. do. do. do. Type-writer.
One do. do. do. do. Lady-birds.

Proceedings of the Board of Revenue *re* disposal of applications under the Waste Land Rules.

The following papers were laid on the table:—

Copies of *Planting Opinion* received during the month.

Proceedings of Nilgiri Planters' Association.

Report of operations of Land Records and Agricultural Department in the Madras Presidency for 1896-97.

List of Agricultural implements and machines tested in India during the year ending 30th September, 1897.

A number of back copies of the *Central Africa Times.*

(Signed) C. G. LECHLER, *Chairman.*
(„) ROBERT GOMPERTZ, *Honorary Secretary.*

COORG.

PROCEEDINGS of the Annual General Meeting of the Coorg Planters' Association, held on Tuesday, 31st May, 1898, at the North Coorg Club, Mercara.

PRESENT.—Messrs. W. M. Ball, H. F. Davy, H. R. East, Jas. T. Morgan, G. R. Pearse, W. H. Sprott, C. Thimmiah, R.B., J. Salisbury Trelawny, R. D. Tipping, and H. G. Parsons, *Hony. Secy.* Mr. W. H. Sprott in the chair.

The Honorary Secretary then read the following report for the year, and placed the accounts on the table, which he would have audited before publication, the position being sound enough if members would pay up arrears as soon as possible.

The late President, Mr. John Logan, had gone to England, so the Honorary Secretary had been informed.

Annual Report, 1897-98.

GENTLEMEN,—On behalf of your Committee it is my duty to submit the following report on our work for the past year, and in doing so regret that I shall not be in my place to read you the report for next. Private business demands so much of my time, and the affairs of this Association require such constant attention, that it will be better for me to resign the management into the hands of some other

more capable and energetic member. I retire with a pang of regret, having had four years of interesting work,—work that is simple in some ways, but which demands much of one's leisure if the interests of the Association and of our community are to be honestly protected and advanced.

Crops.—The coffee crop just gathered, although better than 1896-97, was not good, and many may have found it difficult to cover working expenses. The official returns give the crop of 1896-97 at 1,593 tons against 3,650 tons in 1895-96, and the 1897-98 outturn will probably be between the two, say 3,000 tons. Your Committee regret they are unable to report as satisfactorily as our friends on the Nilgiris, who are to be congratulated on the crops referred to in their annual report, and we think that there is no doubt our short fall is due to unfavourable blossoming weather. The prospects for 1898-99 are considerably brighter, and there will probably be a substantial increase on all European estates and some native gardens. "Leaf disease" has not been bad. "Borer" somewhat worse.

The fall in prices and rise in exchange necessitate strict economy in the working of estates, and it is a question whether the system of working Coorg estates as in the early eighties is not better adapted to the requirements of the land and the shrub than that in vogue in recent years.

Tea.—The first tea estate of any area in Coorg is now being opened, and the experiment is one to be regarded with interest. If successful, your Committee believe that the benefits to the Province will be far-reaching.

Mica.—The geological survey of Coorg by Mr. T. H. Holland resulted in the discovery of another industry in mica. Those who have veins of good quality are advised to prospect, for the samples submitted to London experts have received favourable report. It is to be hoped that if anything does come of the discovery, Government will be liberal in the treatment of those who have not mining rights.

Chief Commissioner.—Colonel Robertson at Pollibetta on 17th January, 1898, received a deputation of your Committee. A report of the meeting has been circulated amongst you, and we are now in communication on certain subjects referred to in it.

U.P.A.S.I.—You will have seen the extent of business transacted at this meeting in August, 1897, from the full report in the book of proceedings. There are, however, a few points to be touched on. We were unprepared to actively support the engagement of an Agricultural Chemist. We strongly urge experiments in the matter of improving the strain of our coffee; in fact, we are of opinion that the deficient yield is partly due to the deterioration of the plant and not the soil. The report of the Committee of Inquiry was considered by the meeting in private, and we now await the orders of the Government of India.

It is gratifying to note that the Madras High Court decided in our favour the question of jurisdiction of Act XIII. of 1859.

The Circulars on the Currency Question, placed on the table, are interesting. Your Association recommended that a small Committee in London, consisting of Messrs. Acworth, Mangles and Sanderson, should be appointed to watch our interests and select suitable witnesses to give evidence before the Commission which has just commenced its sitting; the Chairman, U.P.A., has, however, given Mr. Acworth a free hand.

This contraction of the Currency is proving very serious to many of us, and especially those requiring advances against growing crops. Let the security be ever so good, the money is not available. The revenue of Coorg has fallen considerably and will yet go lower. The Government of India may gain in some ways by an arbitrary exchange, but they lose by agriculture and produce, and at the same time create a discontented people not confined to the natives of the country only. The Secretary to the Chief Commissioner in his letter, No. 2051, dated 28th December, 1897, to the Secretary to the Government of India, Home Department, says in para. 3:—

"A remarkable feature in the year's administration was the great scarcity of money due to the plague in Bombay, and the serious curtailment of banking business which followed upon the decline of trade and the difficulty of communicating with that port. Almost all the local bankers stopped making advances, and as crops were only saleable at a loss, the people experienced the greatest difficulty in obtaining advances, even by pledging gold ornaments. This scarcity of money necessarily affected the collections of the Government revenue."

We can from our own experiences endorse these remarks, and what was bad then is worse now: there were no local buyers of coffee in the past year, and owing to the difficulty of procurin money, distress and poverty are severe: moreover, we do not suppos that Coorg is singular at the present moment.

If matters do not improve, some estates may suffer damage tha will take years to repair; for it is not to be expected that mone will come from England with every prospect of having to be returne at a loss.

Railway.—Your Committee regret they have no progress t report, and although the question is broached spasmodically, they d not anticipate that anything will be done beyond perhaps a occasional letter; in fact, situated as we are, little real interest i evinced by Government, and as long as the Railway Department o India is controlled as at present, the prosperity of a province c community will be sacrificed to the interests of rival Railway Com panies. No reference concerning a railway is to be found in th administration report for the year. Your attention is drawn to a article in the *Times* reviewing a paper read by Mr. Horace Be before the Society of Arts on Indian Railway policy.

P.W.D.—The existing roads are being well kept up, but no ne communications opened, the reason being want of funds. Th Ponampett-Wynaad estimate has been passed and the road sanctione but there is no money to complete it. We understand, howeve Rs.20,000 will be spent. Hatti-Madapoor bridges were urgentl pressed on the Chief Commissioner's notice. The divergence of th Mail Tonga renders more conspicuous the necessity of the Pollibetta Sidapur road.

Police.—We have a European Inspector, but no Assistant Super intendent, the excuse again being want of funds. It is difficult fo us to understand this, for we know that there have been sufficien funds to raise the salaries of the higher officials, doubtless to th advantage of the province, but none to supply an Assistant Super intendent of Police.

The duties of District Magistrate and Police Superintendent ar still combined.

Forests.—The grazing question having been finally disposed o to the satisfaction of those concerned, it is to be hoped that th subject may be considered finally closed. Your Association has ha no complaints during the year. The area of Government Forest remains the same.

Postal.—We understand that the Mail Tonga Service has bee extended for five years, and the mails now run *viâ* Pollibetta, Sidapu and Mercara, thereby covering a greater mileage through th Province. The alteration should be of benefit to the public gen rally, although the mails may take longer to reach Mercara.

The sale of quinine powders of 5 grains each at all Post Office should be noticed; the sale last year amounted to 14,901 powde and is increasing. We regret to observe, however, the price ha been raised.

Cash.—The Accountant-General has received our thanks fo granting Rs.1,000 drafts on Mercara Treasury; the concession is the greatest value, seeing that some of the leading discount agent have discontinued business, and for the benefit of South Coorg it i hoped that Veerarajendrapett Treasury will cash drafts in future.

Land Settlement and Survey.—The result shows an increase Rs.60,142 or 19·86 per cent., to which add the Land Record less th increase on the revenue demand since 1892-93 comes to 32·84 pe cent. It must be pointed out that probably 25 per cent. of th increase is due to concealed cultivation discovered by survey; a the same time the increase is very much more than the Gover ment of India anticipated when introducing the survey (*vide* lette No. 133-11, dated 11th January, 1893). limiting the increase to 10·1 per cent. The land revenue per head of population amount to Rs.2-0-7.

General.—As is usual in recent years, it may interest you t touch on points of general interest to our community. Mr. F. E. Carr has been succeeded by Mr. M. E. Couchman, I.C.S., as Di trict Magistrate and Police Superintendent of Coorg, and the be wishes of the Association are with Mr. Carr wherever he is employe for it was with great regret we heard of his transfer.

Our relations with all Government officials has been harmonio in the past year.

The revenue of Coorg collected for 1896-97 amounted to Rs.8,62,30 against Rs.9,65,300 for 1895-96, a decrease of Rs.1,03,000, and th surplus amounted to Rs.2,46,600 against Rs.3,26,800 in 1895-96, decrease of Rs.80,200 caused by decrease in forest receipts, and decrease in collection of revenue of Rs.38,944, of which Rs.25,78 was kept in abeyance.

The Jail made a profit for the year of Rs.9,562, which perhaps indicates scope for private enterprize.

The Land Revenue demand under all heads amounted to Rs.4,55,324, an increase of Rs.59,119 over last year.

Coffee assessment showed Rs.1,51,481, an increase of Rs.18,168 and the Land Record cess brought in Rs.40,366, an increase of Rs.5,463. It would be interesting to know the cost of the Land Record Department as compared with the cess collected; but no account of this can be found in the Government journals to which we have access.

The area of coffee land amounts to 109,385 acres against 84,991 in the previous year, an increase of 24,394 acres, of which 31,786 acres are held by Europeans and 77,649 by natives; the increase is due to the correct area having been discovered by survey. It is difficult, however, to determine the cultivated area, for it is well known that much land owned by natives is practically abandoned.

Labour was abundant during the year, but an unfavourable blossoming season, and then an abnormal monsoon, all told against a profitable yield, and if the official returns are correct, which is doubtful, the coffee crops ending with 1897 must have been one of the shortest on record.

In conclusion, we have to record with regret the deaths of Mr. William Wright, an old member of this Association, and Mr. Ch. Karmubiah, who had recently joined us. It is also fitting for us to offer our sincere regret at the death of the Rev. A. Fennell, who was a staunch supporter of the Association in its early years, and one who took the keenest interest in the planting enterprize.

The accounts are laid on the table, showing a surplus of Rs.203-14-9 if all outstandings are recovered and dues paid. We subscribe Rs.400 to the U.P.A.S.I., and have 40 votes; your delegates did not deem it advisable to commit you to a larger subscription for the present. The question of individual subscriptions to the U.P.A. having been settled in this way, it remains to be seen how it will work.

The year opened with a membership roll of 77, three resigned and three new members joined; we have lost by death two, and have had to write off one, leaving 74.

Your Committee, President and Honorary Secretary now tender their resignations, and ask you to open the ballot papers for the election of officials for the new year.

Your retiring Honorary Secretary returns his best thanks to all those who have assisted him for the past four years, and these years will be found to have been of more than passing importance when the history of our Association comes to be written. With hardly one exception he has had most cordial relations with all members of the Association, and although wishing to retire from active work, his interest will not abate; and whatever judgment you may pass, let him assure you that the interests of this Association and all brother planters have always been his first consideration.

Proposed by Mr. Sprott, *seconded* by Mr. Ball, that the Annual Report be accepted. Carried *nem. con.*

Ballot.—The following gentlemen were elected for the year:—

President.	*Honorary Secretary.*
James Chisholm, Esq.	H. G. Parsons.

Committee.

NORTH.	SOUTH.
W. M. Ball.	A. Bopanna.
H. R. East.	E. M. Breithaupt.
E. A. Fennell.	J. S. Gerrard.
E. Meynell.	H. G. Grant.
Jas. T. Morgan.	A. Lambert.
W. H. Sprott.	J. Rose.

Currency Committee.—*Proposed* by Mr. Ball, *seconded* by Mr. Morgan, "that the Honorary Secretary do write immediately to the Secretary, U.P.A.S.I., calling attention to this Association's letter, dated 8th May, 1898, with a request that the opinion therein expressed may receive every consideration." *Carried.*

Several circulars on the subject from the Secretary, U.P.A.S.I., were read and recorded.

Tonga Service.—*Proposed* by Mr. Trelawny, *seconded* by Mr. Sprott, "that the Mail Tonga Agent be written to pointing out the inefficient state of his establishment with a hope that now his contract has been extended for some years there will be a marked improvement." *Carried.*

In speaking to his resolution, Mr. Trelawny gave some illustrations in support of his complaint and was corroborated by others.

Circulars, U.P.A.S.I., dated 24th March, 18th April, 19th April, 21st April, 23rd April, 27th April, 3rd May, 4th May, 5th May, 18th May, 27th May.

Resolved that the Annual Meeting of the U.P. Association be opened on Tuesday, 9th August, as suggested by the Chairman.

Honorary Secretary.—Messrs. Ball, Morgan, Sprott and other members present urged the retiring Honorary Secretary to withdraw his resignation, and several members having spoken with appreciation of the work of the Association, it was *proposed* by Mr. Morgan, *seconded* by Mr. Davy, "that a hearty vote of thanks to Mr. Parsons be recorded for the very able manner in which he had conducted the work of the Association during the past year, and that the Meeting record with pleasure his consent to accept office for another year." *Carried* unanimously.

Mr. Parsons, in thanking the meeting and those members present who had spoken in so friendly and complimentary a manner of the work done, was glad again to undertake, to the best of his ability, the duties of Honorary Secretary, and in doing so begged to return his warmest thanks to all members who had shown such confidence in him as the ballot papers revealed. In fact, his re-election was so pronounced that it would almost amount to discourtesy to refuse office, unless for some insuperable cause.

He thanked them all for the honour, and would do his best in the interests of an industry upon which their means of livelihood and happiness so largely depended.

The following papers were laid on the table:—

Report of S. Coorg Coffee Stealing Prevention Fund to 31st May, 1898.

Lower Pulney Planters' Association Meeting, 12th February, 1898.

North Mysore Planters' Association Meeting, 28th February, 1898.

Wynaad Planters' Association Meeting, 2nd March, 1898.

Shevaroy Planters' Association Meeting, 7th March, 1898, 4th April, 1898.

Central Travancore Planters' Association Meeting, 9th April, 1898.

Nilgiri Planters' Association Meeting, 13th May, 1898.

Land Records and Agriculture Report, Madras Presidency, 1896-97.

With a vote of thanks to the chair, the meeting ended.

H. G. PARSONS, *Honorary Secretary.*

Next meeting, July, at Pollibetta.

ROUND THE BUNGALOW.

NOTES BY A "PLANTER'S WIFE."

Mushroom baskets. Make some puff paste; roll it out very thin; line some small moulds with it, filling up the centre with barley or rice that they may keep their shape till baked, when it must be removed. Fill the inside of these moulds with mushrooms and tomatoes minced; pound this mixture in the mortar with a shalot, one ounce of butter, a tablespoonful of thick white sauce, into which a few drops of lemon have been squeezed. Some of the puff paste should have been twisted into lengths bent to the shape of handles, and baked at the same time as the puff paste. Put the handles in, and decorate with fried parsley and preserved barberries. These baskets can also be filled with lobster, chicken, or game.

Mushroom stew. Take some mushrooms, peel them and lay them flat on a dish with the gills up, then sprinkle well with pepper and salt and leave them for an hour or two, then place them carefully in a saucepan in which one ounce of butter should first be melted, stew gently over the fire until the mushrooms are tender, add half pint of new milk and bring to the boil when it should be thickened with one or two ounces of flour, mixed with cold milk until it is as thick as cream. Add this to the mushrooms and milk and boil for a few minutes, pour the mixture over buttered toast and serve hot.

Mushroom omelet. Break three eggs into a basin and whip them till well mixed; add pepper, salt and the mushrooms chopped. Melt one ounce of butter in the omelet pan; when the butter is quite hot pour the egg mixture into the pan, stir quickly to prevent sticking. Keep shaking the pan to prevent the omelet from sticking or burning, spread it over the bottom of the pan to let it cook through, and watch it carefully. When just set, take a knife and put it under the omelet and fold the omelet over. When the omelet is of a pale brown colour, turn it out of the pan into a hot dish, and serve at once.

The mushrooms can be chopped up in the egg mixture, or can be made into a puree, and inserted between the folds of the omelet after it is folded.

Mushroom rissoles. Required: Pastry, mushrooms, eggs, and crushed vermicelli. *Method.*—Stew some mushrooms when cooked, mince them and put them on a plate to cool. Roll out some good short crust very thinly; it can hardly be too thin; stamp into rounds, brush the edges with egg, and lay a spoonful of the minced mushroom in the centre, double the pastry over, and join the edges firmly. Brush over with egg and roll in crushed vermicelli. Fry in hot fat, garnish with fried parsley.

Pigeon en Ragout de Crebettes. Prepare a couple of pigeons, cut them in half, and put them in a stew pan with a glass of sauterne, half a pint of stock, a sprig of parsley, two cloves, pepper, salt, and a shalot; simmer till cooked, strain the gravy. Now put an ounce of butter with a dozen button mushrooms and two or three dozen skinned prawns into a saucepan with a tablespoonful of flour and the gravy the pigeons were stewed in; simmer this for half an hour, then thicken it with a gill of cream and two yolks of eggs, add some finely chopped parsley and a grate of nutmeg. Dish up the pigeons with the mushrooms and prawns in the centre.

HEALTH AND HARD MUSCLES.

IF John Simpson were not a blacksmith we might not have occasion to allude to him at the very outset of this writing. But he *is* a blacksmith and will thus serve an important purpose; that, too, without having to put on his leather apron to do it.

And he will do it by standing in front of his forge for five minutes while we all take a look at him. He is a strong and robust man, as Mr. Dickens's Joe Gargery was—as all blacksmiths ought to be. Ought to be, I say. But *are* they?—as a matter of fact? No, they are not—not by many a length of nail rod.

Now it is somehow a common notion that all men who work hard, especially amid rough surroundings and in the fresh air, are apt to be vigorous, healthy fellows; they are supposed to joke at doctors, to have no use for apothecaries, and even to regard undertakers as the necessity of a distant future. Is this view a true view? Are health and hard muscles always found together? Take your time to think. Meanwhile we will hear what Mr. Simpson himself says:—

"Up to the spring of 1885," he writes in a letter dated May 5th, 1893, "I was strong as most men—perhaps stronger than most. Then I began to suffer from illness. My victuals and I had a falling out. After every meal I had great pain and fulness of the chest. Then I got into such a condition that I had these feelings nearly all the while. I tried to avoid them by eating nothing but light food, but the result was just the same. I think a morsel of bread would have hurt me almost as much as a round of beef. Then I began to lose weight, and had all I could do to keep up with my work. The doctor gave me medicine but I got no help from it.

"I was wondering how this would end when I heard of Mother Seigel's Curative Syrup and bought a bottle of it from Mr. James Crossley, the grocer at Mile Walk. The effect was speedy. It appeared to go straight to the right spot, and it wasn't long before I was able to eat without any pain to follow. Then my strength and flesh gradually came back, and ever since I have done my work as easily as I did before the disease, whatever it was, overtook me. (Signed) John Simpson, Cliviger, near Burnley."

Now, about that health and hard muscle question that I put to the reader; what's the answer? Why, of course, the answer is what any intelligent man would make who thinks with his eyes open. No; health and hard muscles are not always found together. But let us look sharp and commit no errors. The facts run this way: While a man cannot grow strong without a certain degree of health, it is also true that a notable amount of muscular power is consistent with both organic and functional trouble of the stomach, liver, kidneys, or heart. A man may be able to lift 500 pounds, and drop dead within a minute after he does it.

Sailors, farmers, miners, drivers of trams, 'busses, &c., outdoor labourers of different sorts (especially after reaching and life) nearly all fall victims to rheumatism, nervous debility, or dyspepsia. Yes, and do hard work for years just the same.

I said "*or*" dyspepsia. Leave out the "or" and say dyspepsia—dyspepsia only—and you have struck bottom. This produces all the other maladies; they are merely results and symptoms of it. There no keeping clear of it by running off to sea, working on a farm, diving down into a mine. No matter where you go or what you d indoors or out, clerking in the Bank of England, or driving t locomotive of the Scotch Express—*dyspepsia* will get hold of you you give it a chance. And most men do *that* as if they were as eag to be ill as they are to be rich. Which reminds me to tell you in subsequent article how to avoid dyspepsia. For this time I can on speak of how to cure it. Imitate John Simpson's example. Do wh he did. And remember that stalwart men (all unconscious) oft stand nearer a bed of pain, nearer death, than do the feeble wom whom they pity.

MARKET REPORT.

COFFEE.

Messrs. R. J. Rouse & Co's Weekly Coffee Report (March 6, 1898) says:

Auctions were resumed yesterday after a week's interval and t large supplies brought forward met a steady demand at about previo values.

No East India was offered.

Central American kinds, consisting chiefly of Costa Rica, attracted f competition, and the heavy quantities catalogued were nearly all dispos of at steady prices.

Futures have been slightly firmer again this week on the continu rise in the Brazilian Exchange, but very little business has been passi

C. M. & C. Woodhouse's Prices Current of the 12th May afford an inte esting comparative statement of the present prices of coffee from the differe districts of the world.

Sales include the following, viz.:—
